Diseases of the Bones and Joints. By Joel E. Goldthwait, M.D., Charles F. Painter, M.D., Robert B. Osgood, M.D. Cloth. Pp. 685, with illustrations. Price, $6. Boston: D. C. Heath & Co., 1909.

The authors of this book have not attempted to write on orthopedic surgery, but have developed and amplified a number of papers previously published into this very considerable volume of clinical studies. It seemed best to them to include only those diseases which are most common, and to endeavor to give a concise statement of such matters pertaining to etiology, diagnosis and treatment as they have found helpful and satisfying to the patient and suggestive to the physician.

The book is divided into three sections. The first, entitled "Tuberculosis of the Bones and Joints," really comprises only tuberculosis of the joints and so much of the bone ends as are practically always involved in joint tuberculosis and pass ordinarily under the name of joint tuberculosis.

The second section, "Non-Tuberculous Diseases of the Joints," will be found to be the most interesting part of the book. It comprises infectious arthritis, atrophic arthritis, hypertrophic arthritis, lipomata, neoplasms and their relation to joint surgery, hysteric and functional joints, and the operative technic and mechanical treatment of chronic non-tuberculous joint disease. No one in this country has had such abundant material or has given the subject such thorough and conscientious a study as have the authors. Each year we are all seeing more and more of these cases, and learning to differentiate them from tuberculosis, with which not long ago they were generally confounded. No longer are we justified in passing these cases from one to another as hopeless cases for which nothing useful can be done. We know now that it is our duty to look earnestly for the cause, and finding it to remove it. If we do this the progress of the disease is stayed, and local treatment will be of use and some improvement may be confidently expected. This second section alone is sufficient warrant for the purchase of the volume by any general practitioner.

The third section comprises the other subjects in which the authors have been specially interested, from syphilitic bones and joints, osteomyelitis and rachitis on the one hand to flatfoot, aneurism, round shoulders and the use of plaster of Paris on the other hand, not by any means omitting the pelvic articulations and flexed scapulæ. As a treatise on diseases of the bones and joints the book is disappointing; as a series of clinical studies by earnest students and careful observers in the field of orthopedic surgery, it is most valuable and satisfying.

Walsh's Physicians' Handy Ledger. A Companion to Walsh's Physicians' Combined Call-Book and Tablet. Half Leather. Pp. 600. Price, $3.50. Washington, D. C.: Ralph Walsh, 1804 H Street, N. W.

This book is intended as a companion to Walsh's Physicians' Combined Call-Book and Tablet. It is of a very convenient size, 7 by 10, containing 600 pages, 1 page for each patient. This record would appear to be particularly useful by reason of the fact that it not only contains in a very small space, the amount due the doctor, but shows when service was rendered, and how. The book is well bound, opening up easily at any page, and also contains an index.

Protozoology. By Gary N. Calkins, Ph.D., Professor of Protozoology in Columbia University, New York. Cloth. Pp., 341, with 129 illustrations, 4 colored. Price, $3.25 net. Philadelphia: Lea and Febiger, 1909.

This book gives a comprehensive and authoritative presentation of modern protozoology. While protozoa are considered primarily from the biologic point of view, physicians can be fully assured that the pathogenic protozoa are not at all neglected. Professor Calkins has wisely chosen to base the book on broad biologic principles, knowledge of which is essential for the successful application of protozoologic facts to medical problems. The general organization and the physiology of protozoa; the protoplasmic age of protozoa; conjugation, maturation and fertilization of protozoa, are clearly and adequately discussed in the first part of the book, after which come chapters on parasitism (including a discussion of protozoa and the cancer problem, in which no radical views are championed); on the pathogenic flagellates, on the pathogenic hemosporidia, and on the pathogenic rhisopoda. There is a good bibliography, an author's and general index. The need that has existed for a book of this kind is well satisfied by Professor Calkins' work, which admirably fulfils all reasonable demands from the medical point of view.

The Physician's Visiting List for 1910. Flexible Leather, with Pocket and Flap. Price, $1.00 net. Philadelphia: P. Blakiston's Son & Co.

A welcome annual visitor—one of the best of its kind. Neat, handy and compact.

A Manual of Laboratory Methods. By E. M. Perdue, A.M., M.D., Professor of Histology, Bacteriology and Clinical Diagnosis in Hahnemann Medical College, Kansas City, Mo. Cloth. Pp. 188, with illustrations. Price, $1.50. Kansas City: Burton Pub. Co., 1909.

This little book is intended for use by students as a laboratory guide and is in no sense a text-book. It gives in semitabular form directions for embedding and staining tissues, for making cultures of and for staining bacteria, for examination of gastric contents and other body fluids and secretions, for examination of water, etc. An appendix contains tables of weights and measures, lists of Gram-positive and Gram-negative bacteria, stains and reagents, normal and decinormal solutions, etc.

PRACTICAL DIETETICS, with Special Reference to Diet in Diseases. By W. Gilman Thompson, M.D., Professor in the Cornell University Medical College. Fourth Edition. Cloth. Pp. 928, with illustrations. Price, $5. New York: D. Appleton and Company, 1909.

The wide relations of dietetics impose an enormous task on the author who attempts to present the subject in all its relations in an up-to-date manner. The rapid advance of knowledge in all directions renders frequent revision of such a work necessary. Dr. Thompson's work aims to present a practical exposition of the dietetic treatment of all diseases which can be specially influenced by food. To do this and to meet the needs of the general practitioner growing out of the advance of dietetic science, the entire work has been rewritten and considerable additions made. That the result is an eminently practical and useful work is evident. The great value of the scientific data is admitted, but these facts need to be supplemented and interpreted by clinical experience. Calorimetric calculations and metabolism experiments are very interesting, but their application to the individual, and especially to the patient, is not always easy. Thompson is not inclined to accept the lower standard for proteins recommended by Chittenden and Fisher, or to sanction entirely the adoption of Fletcherism. He does not always commit himself on disputed questions.

The diagnosis of diseases of the stomach by laboratory methods is touched on, but in a rather unsatisfactory way. It is hard to see how this matter is properly included within the scope of the book, which does not give other diagnostic methods, but if such subjects are to be discussed it seems hardly worth while to give space to utterly unreliable methods like salol test for motor power and the potassium iodid test for absorptive power. In many other places it is evident that the newer researches on the stomach and intestines have not been fully utilized in revising the work.

In spite of the few defects which may be found on critical study, we have to thank Dr. Thompson for a volume that will in general prove a valuable guide to the physician in a field in which instruction is greatly needed.

A SELECTION OF CASES ON MALPRACTICE OF PHYSICIANS, SURGEONS AND DENTISTS. By Martin J. Wade, Professor of Medical Jurisprudence in the College of Medicine, and Lecturer in the College of Law, State University of Iowa. Cloth. Pp. 896. Price, $4.75. St. Louis: Medico-Legal Publishing Co., 1909.

The great value of this volume and the amount of work expended in compiling it may be surmised from the statement made in the preface that "this volume contains practically every (malpractice) case of any importance which has been decided in the courts of last resort in this country and also the leading cases in England."

The cases are arranged in chronological order, the first one occurring in 1767, the last one in July, 1908. The decisions are all given in full so that all the points in connection with any case are clearly set forth. As a rule, to which there are few exceptions, physicians know far too little of the obligations placed on them in the care of the sick. The question whether all of these obligations are just or not is not to be discussed here; but that they exist is very forcibly shown by the discussions handed down by the learned judges in the cases detailed in this volume. It therefore behooves every physician for his own protection to familiarize himself with the facts as they exist, for in no other vocation is one so liable, at a time least expected and under circumstances least deserved, to be mulcted out of the savings of years of hard work, as in that of the practice of medicine. This work, therefore, should be carefully read by every physician, be he surgeon, internist or specialist, until he is thoroughly informed of the legal duties and obligations assumed in the care and treatment of the sick.

THE MEDICAL RECORD VISITING LIST OR PHYSICIANS' DIARY FOR 1910. Flexible Leather, with flap and pocket. Price, $1.50. New York: William Wood & Co.

Compact and concise as ever, the annual edition of this memorandum book will be welcomed by many who have come to depend on it for the pocket keeping of accounts. The data in the front part have been changed somewhat.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

CALIFORNIA: Los Angeles, December 7. Sec., Dr. Charles L. Tisdale, Butler Bldg., San Francisco.
DELAWARE: Regular, Dover, December 14; Homeopathic, Wilmington, December 14. Secretary of the Medical Council, Dr. H. W. Briggs, Wilmington.
IOWA: State House, Des Moines, Dec. 7-9. Sec., Dr. L. A. Thomas.
KENTUCKY: The Armory, Louisville, December 14. Sec., Dr. J. N. McCormack, Bowling Green.
MARYLAND: 1211 Cathedral St., Baltimore, December 14-17. Sec., Dr. J. M. Scott, Hagerstown.
PENNSYLVANIA: Regular and Homeopathic, Philadelphia, December 14-17; Eclectic, Harrisburg, December 14-17. Secretary of the Medical Council, Nathan C. Schaeffer, Harrisburg.
VIRGINIA: Lynchburg, Dec. 14.17. Sec., Dr. R. S. Martin, Stuart.

Florida May Report

Dr. J. D. Fernandez, secretary of the Regular Board of Medical Examiners of the State of Florida, reports the written examination held at Tallahassee, May 19-20, 1909. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 45, of whom 40 passed and 5 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
University of Alabama (1908) 82, 83;	(1909)	91
Atlanta Coll. of Phys. and Surg. (1907) 82;	(1909)	87
Medical College of Georgia (1907) 77;	(1908)	86
Atlanta School of Med. (1908) 80, 83, 87, 96;	(1909) 82,	83, 84, 88, 89, 90.
Hospital College of Medicine, Louisville	(1904)	75
Tulane University of Louisiana	(1908)	89
College of Physicians and Surgeons, Baltimore	(1887)	84
Barnes Medical College	(1895)	83
Marion Sims College of Medicine, St. Louis	(1892)	79
Mississippi Medical College	(1909)	78
Lincoln Medical College	(1897)	76
New York University Medical College	(1896)	91
Leonard Medical School (1908) 80;	(1909) 76,	94.
North Carolina Medical College (1908) 92;	(1909) 82, 84,	87
Medical College of Ohio (1895) 84;	(1904)	82

Medicolegal

Health Powers Versus Private Rights

The Supreme Court of Vermont says, in the case of State Board of Health vs. Village of St. Johnsbury and others (73 Atl. R. 581), that a statute of that state gave the board the general oversight and care of all waters used by any cities, towns, villages, or public institutions, or by any water or ice companies in the state as sources of water supply, and authorized the board to prohibit any town, city, village, public institution, individual, or water or ice company from using water or ice from any given source whenever in its opinion the same was so contaminated, unwholesome, or impure that the use thereof endangered the public health. This statute cannot be said to be palpably in conflict with the constitution, state or federal; nor can it be confidently asserted that the means prescribed by it have no just relation to the protection of the public health and the public safety. It must be held, therefore, that the board has authority, if properly exercised, to restrain the defendants, as it did, from the furnishing and the use of the village water for domestic purposes until, in the opinion of the board, the danger to the public health ceases.

It was contended that no order could lawfully be made by the board in restraint of the personal liberty of the citizen, for, if water was furnished by the village in its mains and taken into the houses, the board had no authority to punish those who used it for domestic purposes; that the owners of the houses had the right to drink it, and their tenants had the same right, even though forbidden, etc. But the right of the people of the state by their legal representatives of governing and regulating the internal police of the state embraces such reasonable rules and regulations, established directly by legislative enactment, as will protect the public health and the public safety. And the state may invest local or state boards created for administrative purposes with authority in some proper way to safeguard the public health and the public safety. The way in which these results are to be accomplished is within the discretion of the state, provided the powers and functions of the general government are not thereby infringed, nor any constitutional provision of the state or the United States.

If the mode adopted by the state for the protection of the public health and safety of its local communities proves to be objectionable, inconvenient, or even distressing to some, if nothing more can reasonably be affirmed against the statute, the answer is that it is the duty of the constituted authorities primarily to keep in view the welfare and safety of the many, and not to permit their interests to be subordinated to the wishes or the convenience of the few.

Questionable and Inadmissible Evidence in Malpractice Case

The Supreme Court of Michigan says that the plaintiff in the malpractice case of Farrell vs. Haze (122 N. W. R. 197) sustained, on a Tuesday, an injury to his right foot, ankle and leg—a "Potts fracture." The defendant was employed, and put the injured member in a plaster of paris cast. As things went, if he cut—opened—the cast on Wednesday, he was admittedly without fault. If he did not cut it until Sunday, and if the foot and leg were then in the condition described by plaintiff and his witnesses, he did not exercise ordinary professional skill and judgment, and for the resulting injury he was liable. The defendant testified that he cut the cast on Wednesday, the next day after the injury. He kept books and employed a bookkeeper. It was his practice to make a memorandum of visits to patients on prescription blanks and to hand the memoranda to his bookkeeper for entry by her into a daybook. She also kept a ledger. The slips, daybook and ledger were produced in court, and were offered and received in evidence over the objection that they were all immaterial, incompetent and self-serving. The purpose in offering them was not to show the state of an account with the plaintiff, but to corroborate the defendant's testimony concerning the date of cutting the cast by a memorandum made by him at the time. The court avoids deciding whether the memoranda were really admissible in evidence for the purpose stated or not. It merely says that, assuming, but not deciding, that the memoranda were evidence to the jury of the facts contained in them, it was within the discretion of the court to allow them to be taken to the jury room, and it was not an abuse of that discretion to refuse to allow them to be taken there.

It was one of the undisputed facts in the case that the bones in the foot and ankle became diseased, and that this condition rendered amputation necessary. What caused the bones to become diseased? The plaintiff's contention was that most probably the cause was the treatment received from the defendant. But the opinions of the experts did not support this contention. It is not enough to show a state of facts equally consistent with unskillfulness and negligence and with skillfulness and due care. Therefore the jury should have been instructed by the judge, as requested, that: "The question whether the loss of the plaintiff's foot was attributable to anything that the plaintiff claims the defendant did or omitted to do is a scientific question, which the jury cannot determine for itself, and can be answered only by an expert; and inasmuch as no expert or medical man or surgeon has stated that the loss of the foot in his opinion came from anything the defendant did or omitted to do, therefore I charge that you cannot take the loss of the foot into consideration in this case or hold the defendant liable therefor."

The plaintiff produced in court, but under covering, what were stated to be the bones of the amputated limb, and proposed to exhibit them. The court is of opinion that they should not have been produced or offered in evidence. It is conceivable that if they were in the same condition they were after the injury, and while the defendant was treating the limb, the extent and nature of the various fractures produced by the injury being in question, their examination and perhaps their production in court would have been of value. But the plaintiff has proved that various portions of the bones were removed before the amputation took place. He had proved that their condition before and at the time the limb was amputated indicated a gradual and continuing disintegration of the bones from some cause which was active long after the defendant ceased to treat the injury. It could not be apprehended that the jury would be enlightened or instructed by an examination of the remains by themselves or by witnesses in their presence.

Again, the court holds that one who is not possessed of the requisite qualifications of a physician and surgeon cannot be exempted from liability on the ground that his mistake was caused by an error of judgment. But want of requisite qualifications is not shown by proving that he was discharged by a patient and another physician hired who changed the treatment.

A physician, who testified that the defendant possessed the skill of the average surgeon, was asked, on cross-examination, if he knew of the defendant's treating certain cases, and particularly one where he was discharged and the treatment entirely changed. The court says that it could perceive no purpose in asking these questions, except the one of producing by incompetent means and without tendering the necessary issue the impression that the defendant was lacking in professional skill because he had failed in other cases to satisfy his patients and the physician who succeeded him.

The judgment obtained by the plaintiff is reversed and a new trial granted.

Sufficient Evidence as to Practicing Without a License

The Supreme Court of Washington says, in the case of State vs. Dodson (102 Pac. R. 872), where it affirms a conviction of practicing medicine without a license, that it was contended that under the provision of the statute the state did not make out a prima facie case against the defendant, because it did not show that he had not been a practicing physician prior to the enactment of the statute under which he was convicted. But it is held sufficient that the state showed by the clerk that the defendant had not filed a license in his office, and that none had been filed. The statute makes the records of the clerk's office prima facie evidence of the existence or nonexistence of a license.

Again, the court says that the statute provides that "any person shall be deemed as practicing medicine within the meaning of this act who shall have and maintain an office or place of business with his or her name and the words physician or surgeon, "Doctor," "M. D.," or "M. B." in public view, or shall assume or advertise the title of doctor or any title which shall show or shall tend to show that the person assuming or advertising the same is a lawful practitioner of any of the branches of medicine or surgery in such a manner as to convey the impression that he or she is a practitioner of medicine or surgery under the laws of this state." Evidence to prove that the defendant had done the things prescribed by the statute was offered, and it was for the jury to determine the weight of such evidence.

1 Aspects of Rocky Mountain Spotted Fever as Shown by Recent Investigations. H. T. Ricketts, Chicago.
2 *Creosote Treatment of Pulmonary Tuberculosis. B. Robinson, New York.
3 Plea for a Reform in Medical Education. E. Souchon, New Orleans.
4 Idiopathic Hydropneumothorax with Complete Recovery. A. P. Francine, and H. R. M. Landis, Philadelphia.
5 A Fragmented Filiform Bougie Removed from the Male Urethra Without Operation. V. C. Pedersen, New York.
6 *A Statistical Analysis of over 68,000 Cases of Typhoid. A. K. Sallom, Philadelphia.
7 Acute Gangrenous Cholecystitis; Gall-Stone in the Cystic Duct; Perforation of the Gall-Bladder. E. Williams, Patterson, La.

2. **Creosote Treatment of Pulmonary Tuberculosis.**—Robinson repeats that by the combined, persistent, intelligent use of beech-wood creosote internally and by inhalation, many patients may be saved who otherwise would die. In nearly all cases, no matter what the stage of the disease, much relief to symptoms may be obtained. This treatment is simple and inexpensive, and interferes with no other rational doing. It greatly supplements that doing. Creosote treatment is of great value as a preventive treatment, when pulmonary tuberculosis is a menace to the individual, either by reason of constitutional tendency, exposure to infection, or both. To judicious rest, when required, fresh air, and proper food, add creosote treatment, with or without lime salts, and there is at present little or nothing in the way of further treatment to insist on.

6. **Typhoid.**—This report represents a study of the cases of typhoid fever which have occurred in Philadelphia during a period of eleven and one-half years. From January, 1898, to June, 1909, there occurred 68,943 cases. Of this number 8,102 patients died, giving a mortality of slightly over 11.75 per cent. The greatest number of cases occurred in February, there being an average of 759 cases. January is a close second, averaging 694 cases. The average number of cases for each month then gradually falls, reaching its lowest ebb during July. It again rapidly rises, reaching a second maximum during September. During October and November it falls, to rise again in December. From the data at hand Sallom believes that the filtered water has been instrumental in the reduction of the number of cases of typhoid, for it appears that while the number of cases was greatly reduced in the district receiving filtered water, typhoid fever was still prevalent in the district not receiving filtered water, and in this manner increasing the general number for the entire city.

Boston Medical and Surgical Journal

November 18

8 Recent Experimental Work on Hemorrhagic Conditions. W. P. Lucas, Boston.
9 *Treatment of Summer-Diarrhea as Influenced by Etiology. C. H. Dunn, Boston.
10 Hodgkin's Disease in a Child. H. De Wolf, Providence, R. I.
11 *Cure of Club-Foot in Infancy without Operation. A. Ehrenfried, Boston.

9. **The Treatment of Summer Diarrhea.**—The treatment of the diarrheal diseases prevalent in the summer should, Dunn believes, be based on the known facts as to the etiology of the disease. This may, for the four types, be briefly summarized as follows: 1. Acute nervous diarrhea: Castor oil or calomel, temporary dilution of food, paregoric in persistent cases. 2. Acute intestinal indigestion, type of deficient secretion, irritative diarrhea: Castor oil or calomel, boiled water for twenty-four hours, barley water or other carbohydrate solution for a second twenty-four hours, followed by dilute milk modifications, with low fat and casein and high sugar and whey proteid; irrigation of the colon in long-standing cases. 3. Acute intestinal indigestion, fermentation type, fermental diarrhea: Castor oil or calomel, boiled water for twenty-four hours, barley water for the second twenty-four hours; avoid proteid foods, such as albumin water or whey. It is safest not to begin milk-feeding till the third day, and then very cautiously, with modifications low in fat, whey proteid and casein. Living lactic acid bacilli are a specific against this disease and are given in ripened fat-free milk or in buttermilk, which is best begun after forty-eight hours; subsequent feeding according to the type of indigestion also present; irrigation of the colon twice daily; antidysenteric serum in resistant cases.

11. **Club-Foot in Infancy.**—The treatment which Ehrenfried has practiced consists in manipulations and retention. The manipulation is performed after this fashion: The ankle is held firmly by the fingers of the left hand. The right hand gently but firmly grasps the forefoot, which, the heel being fixed, should be gradually abducted as far as possible. If the manipulations cause pain the infant will become rebellious and spasm of the muscles will be set up, which will interfere with the desired object. This abduction should be repeated several times, each time carrying the foot out as far as possible and holding it a few seconds, allowing it to return gradually. Then the same procedure, supplemented by eversion of the foot, should be repeated for a minute or two. The entire foot should be gradually everted until the sole looks outward. Then, with the foot abducted and everted, dorsiflexion at the ankle should be practiced. Finally, the entire foot may be circumducted about the ankle. After the foot has been rendered as flexible as may be by this procedure, it is fixed in the position of greatest correction or overcorrection allowable, by some retentive apparatus. The purpose of this retention is to maintain the stretch on the structure already noted and at the same time to allow the lax opposing structures to contract and to prevent and correct the maldevelopment of the bones of the ankle. Fixation may be had best by means of plaster of Paris. The plaster is applied from thigh to tips of toes, with the knee flexed, so as to prevent the cast from twisting on the leg, and allowing a return of the varus deformity. If the plaster is applied to the best advantage three two-inch rolls are ample in a young infant. Of the first roll, half is used in making a collar about the forefoot. This is applied—the foot hanging relaxed—in such a way, with circulars and reverses, as to lie snugly against the foot. It should extend to the tips of the toes, but should not cramp them or hide their extremities. It should fit closely against the inner border of the great toe, to its very tip, so as to give efficient leverage in abduction. The remainder of the roll is applied in circular turns about the thigh, carried as high up as possible. When the collar has become solid the second roll is applied, in the form of circular turns over the thigh and under the ball of the foot. This roller should always be applied in such direction that the turns, when drawn tight, will naturally assist in elevating the outer border of the foot, and maintaining eversion. The third roller is put on immediately and is used to cover in the knee and heel. The plaster here need not be thick, as it is not essential in maintaining the position; and for the sake of lightness it had best be applied in recurrent turns. Plasters are reapplied every two weeks, each time after thorough manipulation.

Ehrenfried has found it an advantage in some cases to make use of a splint after the plasters have been discontinued. This is made of tin with an upright of heavy iron wire which can be bent so as to give any degree of dorsiflexion or eversion. It is applied to the leg, over sheet bandage. In convalescence it may be worn only at night and the foot manipulated by the mother or nurse in the morning after it is removed and at night before it is applied.

15. **Gastric Ulcer.**—The indications for any surgical treatment of gastric ulcer, according to Einhorn, are as follows:

1. In large, recurrent gastric hemorrhages threatening life, the ulcer ought to be excised in the interval of a gastroenterostomy established, to prevent renewed hemorrhage.
2. Small losses of blood that cannot be checked and endanger life through their persistence require similar treatment.
3. Perforation of the ulcer demands always immediate operation (excision or invagination of the defect and suture) as soon as the diagnosis has been made.
4. An ulcer situated at the pylorus and attended with peristaltic restlessness of the stomach and continuous hypersecretion.
5. Advanced stenosis of the pylorus requires gastroenterostomy.
6. Duodenal ulcers accompanied by pylorospasm and beginning peristaltic restlessness of the stomach.
7. Gastric ulcers with formation of a tumor, no matter where the seat (pylorus, small curvature, etc.), always demand gastroenterostomy, usually with excision of the tumor. If this tumor is situated in the lesser curvature and cannot be resected, it is still curable in case it is caused by simple connective tissue proliferation (callous ulcer formation).

16. **Coordinated Attack on Tuberculosis.**—Results at the Adirondack Cottage Sanitarium show that up to November, 1908, when the records covering twenty-two years are roughly scanned, 52 per cent. of the patients in an incipient stage, 25 per cent. of the moderately advanced, and less than 2 per cent. of those in far-advanced stages are alive. In other words, a patient in the incipient stage has at least twenty-six times as good a chance of permanent recovery as one in the far-advanced stage. In view of the fact that tuberculosis is now said to be so curable that all a patient needs is fresh air (some would deny any tempering of the cold to the shorn lambs), a chair, and some milk and eggs, in view of this, these figures are of importance. Not every patient with tuberculosis will recover, no matter how early his case is diagnosticated, and no matter how soon put under the most approved treatment. But in an early case the patient has twenty-six times better chances for permanent recovery than in a late one.

21 Mastoiditis and Other Complications of Acute and Chronic Suppurative Otitis Media. E. E. Clark, Danville, Ill.
22 Local Versus General Anesthesia. B. M. Ricketts, Cincinnati.

20. **Restoration of Female Pelvic Outlet.**—Crosthwait describes a technic for the average case in which the perineal body has been broken up by laceration of component part or parts with rectocele and pouting vagina resulting. The operation is the open flap-splitting one, giving free exposure of the external sphincter and levator ani and superficial transverse perinei with their fascia. A U-shaped incision is made from just below the orifice of the glands of Bartholin along the mucocutaneous margin. By blunt dissection, the posterior wall of the vagina is separated from the rectum up to the highest point of the rectocele and laterally as far as the scar tissue extends and far enough to give free exposure of the margins of the levator ani muscles and their fascia. This point is important, for the fascia has more to do in restoring strength to the injured parts than the muscle tissue itself.

The second step is to suture the levator ani and fascia. From two to four sutures are required and the suture material should be fifteen-day chromic catgut. It is important that these sutures be placed far enough out to include the fascia. They should be placed so as to lap the edges of the muscles. The next step is to bring up the severed ends of the bulbocavernosus and external sphincter ani and unite them in the perineal center. Then the fibers of the transverse perinei are caught up and inserted in their normal place. This, however, cannot always be done, as those muscles when parted from their insertion often retract so far that they cannot be found. The last step is to suture the flap vertically with buried twenty-day catgut.

The advantages of this operation are said to be: 1. There is exact anatomic approximation of the parts. 2. It gives a permanent cure with full restoration of lost function. 3. It is far less painful during the process of healing, with no sutures to remove. 4. It can be done in far less time than any other method.

29. **Angina Pectoris.**—That the diagnosis of angina pectoris, at least in its milder forms, cannot be made from the history alone, is contended by Butler. The other forms of cardiac pain, of toxic or neurotic origin, the latter especially in women, may exactly simulate a true angina pectoris. After allowing due weight to the age, sex, and detailed history of the patient, it is necessary to ascertain the presence or absence of signs of organic disease at the root of the aorta. On this hangs an enormously important decision. When plain signs of general arterial or aortic disease co-exist with a history of precordial pain, there need be no hesitation in making a positive diagnosis of true angina pectoris. But it is otherwise in patients with cardiac pain in whom, as may happen, the accessible arteries are soft, and who do not present signs of gross aortic or pericardial lesions.

In the election between true and false, organic or functional, there is one physical sign which Butler believes casts the controlling vote. It is so slight, and apparently so insignificant, that one almost hesitates to mention it. It is simply a slight clicking sound, of a harsh or rough quality, accompanying, or following at a barely perceptible interval, the sound of aortic closure. It is not an accentuation of the closure sound of the valve, such as the loud, clean, "cork and bottle" aortic second sound, which is signficant of high arterial tension. Nor is it to be confused with a reduplication of the second sound. The slight harsh click, to which Butler refers, is said to suggest to the ear a definite roughening or thickening of the edges of the aortic cusps. When autopsies have been obtained the findings have justified such an interpretation of this auscultatory sign. If, then, the aortic cusps are roughened, it is certainly a fair inference that the root of the aorta shares in the diseased process. Butler recalls but two cases of true angina in which this sound has not been heard.

32. **Still's Disease.**—Pisek holds that the polyarthritis described by Still seems to be the result of a chronic sepsis, which while not sufficiently potent to completely overpower the young organism, has destroyed resistance by enfeebling the phagocytic power of the blood, and lowering the activity of the lymphatics. This special form of chronic arthritis, he considers, is worthy of consideration by the general practitioner, as the prognosis is not necessarily hopeless.

48. **Treatment of Whooping Cough.**—At the onset of treatment Cushing has found it well to require that for a week or so the patient be kept in bed. Even when the patient is first seen in the paroxysmal stage of the disease, the brief stay in bed is eminently useful, for the control thus secured enables the physician to initiate his measures of isolation and treatment under the most favorable auspices. In the presence of complications of any sort, or when the disease itself is of a severe type, the paroxysms frequent, and vomiting troublesome, confinement to bed is, of course, indispensable at any period of the illness. At night every window in the child's bedroom should be kept wide open. The cold fresh air of a winter night is far the most efficient nocturnal sedative for the cough of pertussis. That the paroxysms of whooping-cough usually occur more often at night than during the day, as described in the books, is entirely due to vitiated air in the sleeping-room. It is an artificial and not an essential feature of the malady. During the daytime the patient should be indoors as much as possible. Running, or romping, or too vigorous play of any sort, loud laughter or screaming, should be avoided as likely to provoke paroxysms.

The child's meals, even when it is about, and the attack is mild, should not be taken at the family table, but eaten in the nursery to secure quiet, slowness of eating, and an easy control of quantity, for overeating almost invariably provokes a convulsion of cough which brings up all the food taken. For quite another reason, too, the child should be kept from the table and from all other unnecessary contact with the adults of the household, and that is, the risk of contagion to the latter if brought in close range of the cough explosions.

Of drugs, belladonna and antipyrin, and for a sedative, heroin or opium, in the form of paregoric or Dover's powder, have served Cushing best. He commences treatment with a belladonna dose after each meal and heroin at bedtime. The belladonna is given in the way Jacobi has so often advised, that is, beginning with a drop, or even a half-drop of the tincture, to anticipate a possible idiosyncrasy on the part of the patient; the dose is increased one drop each day until a point is reached where within an hour from the time the medicine is taken a distinct flushing of the cheeks occurs. In the child this erythema develops, as a rule, before an uncomfortable dilatation of the pupils results; and when the dose is found which occasions it, a distinct lessening in the intensity and number of the paroxysms is ordinarily apparent. Short of this effect, belladonna seems without influence on the disease, but when the flushed cheeks show themselves, betterment is the rule. Six or eight drops of the ticture of belladonna are usually sufficient to produce the desired effect in a child from 6 to 8 years old, and this dose should then be continued for a long period. If, on the other hand, no effect on the frequency of the coughing fits is apparent, the belladonna is omitted, and antipyrin administered in its stead, in a dose of 1 grain for each year of the child's age, in solution, and given 3 times a day after meals. At bedtime an appropriate dose of heroin or paregoric or Dover's powder needs ordinarily to be administered.

61. **Retrodisplacements of Uterus.**—Humiston divides the cases of retrodisplaced uterus into two classes: a smaller one in which active major surgical measures are not required to obtain a cure, and a larger one in which active surgical procedures are necessary. In the first group are all those cases of retroversion of not long standing, and in which there has been no infection or inflammation of the appendages. In most cases of this group miscarriage or labor recently occurred. The prominent symptoms presented are backache, occipital headache, bearing down feeling while in the upright position, frequent but not painful micturition, constipation, disturbed digestion, and an increasing nervousness. Menstruation is increased in amount and frequency, but is not, as a rule, painful. Some leucorrhea is always present. Digestive disturbances are usually prominent. Bimanual examination, as a rule, reveals injury to the pelvic floor and perineum, cervix lacerated, swollen and in axis of vagina. Cervix easily reached with finger, and a continuous resisting body from posterior wall of cervix as far as finger can reach, which is movable. Ovaries can be palpated and are movable and but little increased in size. Fundus of uterus is absent in front. These patients can be cured by curettage, trachelorrhaphy, replacement of uterus, adjustment of well-fitting pessary, and repair of the pelvic floor and perineum by a method that will insure a muscular restoration of the parts.

Unfortunately, he says, 90 per cent. of these cases are complicated when specialists see them, and in these cases, in addition to the above operations, the abdominal cavity is opened and the diseased conditions found dealt with. The results Humiston has obtained with the Gilliam method in 103 cases in three years are highly satisfactory. He has had no deaths in the series, nor have there been complications at delivery in those patients who subsequently became pregnant. All were delivered without artificial aid, except in one case, where low forceps were used. No connection could be traced between the Gilliam operation and the procedure.

62. Abstracted in The Journal, Oct. 2, 1909, p. 1121.

63, 65, 66, 67, 71, 73. Abstracted in The Journal, Oct. 9, 1909, pp. 1217, 1218, 1219.

64. **Operative Enlargement of Pelvis.**—Bell suggests that in order to obviate the dangers of pubiotomy the pelvis might be enlarged by operating in the non-pregnant state, and thus prepare the woman for future delivery. The indications for the operation are, according to Bell: A history of two or more difficult deliveries with child born dead, further attempts to secure a living child by premature delivery, a true conjugate diameter of from 7.5 to 8.5 cm., a dread of Cesarean section, and a strong desire on the part of the patient to give birth to a living child. It is granted that only a comparatively small increase in the pelvic diameters can be secured when operating in the non-pregnant state, yet, in a properly selected case the increase is just sufficient to convert an otherwise dangerously contracted pelvis into a comparatively normal one for future childbearing.

In doing the operation in one case, he followed the method of Döderlein in his operation of pubiotomy at term, and spread the severed ends of the bone 1.5 cm., holding them apart with a small steel retractor which was left *in situ* for ten days. There was very little hemorrhage. Healing was slow; but the patient recovered and walked without any discomfort. The pelvic measurements show an increase in the transverse diameters. This proves conclusively that a distinct enlargement of the pelvis can be obtained by operating in the non-pregnant state and preparing the woman for future childbirth. The question of the advisability of this procedure remains to be determined.

68. **Artificial Anus.**—As the result of an appendicitis operation improperly performed, the patient, a boy, had an artificial anus in the median line, through which all fecal matter had passed for three years and a half, there being complete exclusion of the entire large bowel for that length of time. The patient had not had a natural bowel movement during all this time. Brown believes that the boy undoubtedly did not have appendicitis, but that the original condition was intussusception. One of the most interesting features of this was the condition of the ileum from an obstructed band of the ileocecal valve. As stated, the entire large bowel was out of commission for three and one-half years. The most remarkable condition was an ileoitis obliterans, the ileum having contracted and swollen to such an extent that it was almost impossible to get a small grooved director through it. The appendix was free, but showed that it had participated in the peritonitis brought about by the intussusception and the fecal leakage, but to all appearances this was a secondary and not a primary incident. By means of an ileocolic lateral anastomosis the fecal current was turned back into the large bowel.

96. **Treatment of Drug and Alcohol Habitués with Hyoscin.**—Riewel summarizes his views as follows: 1. The hyoscin treatment will eliminate the desire of drug and alcohol habitués for these drugs, thus eliminating the element which prevents the patient abstaining by force of will power. 2. Having lost the desire they do very well without intoxicants or the drugs as shown by the increase in appetite, gain in flesh and their general improvement. 3. The question of relapse lies entirely in the sincerity and environment of the patient. 4. The favorable alcoholic addicts are those who earnestly desire to discontinue the use of intoxicants and are willing to change their mode of living and environment, but who cannot until relieved of the craving for liquor. 5. Relapse in both drug and liquor cases is not due to a desire nor suffering after the treatment, but to their curiosity to test the necessity of total abstinence, or to the temptations of social life. 6. A single dose of the drug or drink of liquor, even after one year of total abstinence, is very apt to start the craving, resulting in a condition which is no better than before treatment. 7. This method may prove a valuable treatment in apparently hopless cases of opium poisoning. Interesting experiments along this line might be carried out. 8. The one contraindication for this treatment is the presence of Bright's disease. 9. No patient should be treated unless put to bed and watched by competent nurses day and night during the first week.

107 *Appendicitis in Children. A. H. Bogart, Brooklyn.
108 *Acute Anterior Poliomyelitis. Le G. Kerr, New York.
109 Blastomycosis. R. H. Fowler, New York.

107. **Appendicitis in Children.**—Bogart says that appendicitis in children is a comparatively frequent disease, insidious in its onset and rapid in its development, with a decided tendency toward the development of general peritonitis, with a fatal termination if neglected; and that whatever holds good with regard to immediate operation in the adult is doubly true in children, and that in the light of present knowledge no patient should be permitted to go for three days without operation. Bogart emphasizes the fact that the removal of the appendix in a child by a competent surgeon is comparatively without danger and recommends that it be done in every case as soon as a diagnosis has been made, provided that a competent surgeon and the proper facilities can be had to do it. In this and in no other way can the present mortality be reduced.

108. **Acute Anterior Poliomyelitis.**—In one epidemic, between Aug. 7 and Sept. 4, 1909, Kerr observed 53 cases of the disease, and the symptoms of the onset were as follows: Fever, accompanied with diarrhea, 10; fever, cough and diarrhea, 4; fever, vomiting, cough and diarrhea, 12; fever alone, 4; fever and constipation, 7; fever and vomiting, 3; fever and cough, 1; fever, cough, vomiting and constipation, 3; and no symptoms noted, 3. In the remaining 6 cases, the symptoms of the onset were those of a definite disease, associated with the other symptoms, and were diagnosed as follows: four suffered from tonsillitis, 1 from lobar pneumonia and 1 from acute gastroenteritis. From this it is seen that the more suggestive symptoms are the fever, diarrhea, cough and vomiting. With such symptoms present, and nothing else to guide us in the making of a definite diagnosis, we must take the position of withholding the expression of an opinion as to the disease present.

As soon as a child was suspected of having the disease, as indicated by the prodromal symptoms which are suspicious in the presence of a known epidemic, it was immediately placed in a hot blanket pack. The wet blanket was wrung out after being placed in water of the usual temperature, 160 F., and in this the child was wrapped with hot water bottles placed at the feet. The application was sufficiently prolonged to induce a free perspiration. This procedure was followed even in the presence of considerable rise in temperature, but was never repeated. The rather copious drinking of hot water was encouraged. In many instances the vomiting was almost immediately relieved and the free perspiration which was brought about by the hot blanket pack was continued or augmented. But even if the vomiting persisted or seemed to be increased by the ingestion of the hot water, its use was continued, although the amounts given were decreased. The administration of the water was continued for twelve hours.

The bowel was thoroughly emptied by a hot enema and in most of the cases this enema contained 1 ounce of magnesium sulphate and 2 ounces of glycerin to the quart of water. Immediately following the hot enema, the child was given a single large dose of castor oil, and was then placed in bed in a quiet and darkened room and allowed but one attendant. So far as possible the child was prevented from lying on the back. Cold applications were immediately made over the spine and particularly in the lumbar region. This was the procedure during the first twelve hours and no food was allowed during this period. At the end of the first twelve hours the hot enema was repeated and the ingestion of the hot water stopped. For two days the diet was restricted to fluids and if any further action of the bowel was needed calomel in broken doses was used. During this stage only two drugs were used, belladonna and ergot. Both were administered in full doses. Of the number so treated, in no instance was the child afflicted by any paralysis nor was there the further development of symptoms which would lead to the recognition of a definite disease.

114. **Resection of the Male Rectum.**—The technic employed by Lusk includes the use of the combined routes—Rotter's technic of sectioning the descended bowel through the posterior wound after first liberating it through the abdominal approach, and Kraske's position of vertical elevation of the hips with the patient in the dorsal decubitus for suture of the bowel ends, as well as the method Kraske employs in sacral resection of dividing the proximal segment of bowel above the tumor with interrupted cuttings as the stitches are placed.

115. **Postoperative Psychoses.**—Kelly maintains that postoperative psychoses seen often in childhood and the aged, occur also in women in the prime of life, most frequently between the ages of 35 and 45. Anesthesia, physical shock, the kind or severity of the operation are not effective causative agents. Infection, autointoxication, drug intoxication are important factors, but there are many psychoses entirely independent of them. Mild aberrations of a transitory nature are very common. An unstable nervous system, and especially undue anxiety and worry about the operation are the most potent factors in bringing about profound nervous sequelæ. Prognosis is favorable. Prophylaxis consists in quieting and reassuring the patient. In this connection the nurse is most important. Care should be taken to avoid any legal or forensic complications by frankly dealing with the family from the onset of the trouble.

117. **Malignant Leiomyoma of the Uterus.**—Myer records a case which seems to fulfill all essential requirements from both the clinical and pathologic standpoint.

118. **Tuberculosis of the Peritoneum.**—The apparent difference in the incidence of peritoneal tuberculosis in the male and female, Allport believes is apparent rather than real, and such difference as exists is due altogether to the inclusion of the female organs within the peritoneal cavity. The apparent differences in the form of peritoneal tuberculosis are due: (1) to differences in the location and structure of the organs involved; (2) to a recognition of the disease at various stages in its development. Pathologically, the disease has but one form, which unfolds itself along the same morphologic lines as in other parts of the body. Peritoneal tuberculosis is never primary. The most common avenue of entrance is the bowel; next, the lymph glands; next the female genitals. Bowel infection may be secondary to that of the peritoneum, and the female genitals may receive infection in the same retrograde manner. Gravity plays an important part in the spread of intraperitoneal tuberculosis. The same is true of diffusion by contact and continuity.

Temperature of a markedly febrile character is an indication of mixed infection; especially true is this of remittent fever. High leucocytosis and temperature following operative interference are favorable conditions, and indicate good resistance of the individual to the farther progress of the disease. In abdominal operations followed by prolonged fever and delayed convalescence, the possibility of existence of hitherto unsuspected tuberculosis should be borne in mind by the operator. All specimens removed at abdominal operations should be thoroughly inspected for tuberculosis. The theory that ascitic fluid has a protective, curative, opsonic, or otherwise salutary function is incapable of proof. In all cases in which recovery takes place, healing occurs after the resorption of the fluid and through the agency of active hyperemia and adhesions; the adhesion is the force which, here as elsewhere, delimits and excludes the morbid process from becoming a farther power for evil. Statistics, approved by the best modern opinions, show that simple incision with thorough evacuation of the fluid without drainage, increases by a very appreciable percentage the uncertainty and rapidity with which climate, hygiene and diet can effect a permanent cure.

Radical operations, such as curettage, erasion, resection, continued drainage—beneficial in joint surgery—should have no place, except as emergency measures, in dealing with the intraperitoneal lesions of tuberculosis. Drainage, he says, is a "snare of the devil" and is especially apt to be followed by serious and often fatal fecal fistula in the dry forms of tuberculous peritonitis. Statistics show conclusively, he asserts, that its practice leads to evils which are worse than the original disease.

119. **Rupture of Pyosalpinx.**—Bonney reports one personal case and reviews 44 cases recorded in the literature.

123. **Treatment of Diffuse Septic Peritonitis.**—Of the series of 167 cases of diffuse septic peritonitis from appendicitis operated on by Fowler at varying intervals following perforation, up to January, 1909, there have been but fifteen patients operated on within twenty-four hours of the onset. This series does not include any patient operated on for perforation of the appendix within a few hours of the perforation, in which event one finds an appendix congested to a variable degree, free or slightly adherent, a perforation usually in the distal half, with or without the escape of an enterolith, seropurulent fluid, malodorous or not, according to the germ present, moderate in amount and not under tension, a peritoneum which only in the neighborhood of the appendix showed slight change, perhaps hardly any injection of the peritoneal surface. Of such cases Fowler has operated on over 100 patients with no deaths.

Of the 15 patients with diffuse septic peritonitis, 9 were males, 6 were females; 4 were between the ages of 10 to 15; 6 were 15 to 20; 1, 20 to 25; 1, 25 to 30; 2, 30 to 35; 1, 35 to 40; 11 had had no previous attacks; 3, one previous attack; 1, three previous attacks; 15 were twenty-four hours in present attack when operated on; 15 were operated on by an oblique incision; 15 showed free pus under tension when the peritoneum was incised; in 13 the appendix was free, gangrenous and perforated; in 2, it was slightly adherent, gangrenous and perforated; in 14, the appendix was removed in the typical manner, and the stump inverted; in 1, the base was ligated; in 7, the peritoneal cavity was flushed with saline, in 3, with peroxid followed by saline; in 5, no irrigation was used; in 15 cases laparotomy sponges were used to keep back the intestines while removing the appendix; in every case these sponges, when removed were saturated with a purulent material and fibrinous exudate; in 7 cases a glass tube into the pelvis was used for drainage; in 1 case a rubber tube; in 3 cases wicking or gauze to the site of the appendix; in 2, vaginal drainage; in 2, no drainage; the average duration of operation was twelve minutes; in 15 cases the elevated head and trunk posture was employed; 13 patients were given fluids immediately on recovering from anesthesia; 2 were given nothing by mouth for twenty-four hours; 8 received saline enemata every four hours for four doses; 6 nothing by rectum; 1, Murphy irrigation. Average stay in the hospital twenty-eight days. All cases recovered.

Fowler concludes that patients with diffuse septic peritonitis from appendicitis operated on within twenty-four hours of the onset of the disease, i. e., before the peritoneum is infiltrated, recover, providing the primary focus is removed quickly without damaging the absorbing power of the peritoneum, irrespective of feeding or enemas, providing the absorbing power of the peritoneum is properly made use of.

1. **Darwinism and Medicine.**—That a general survey of the relation of Darwinism to the science and art of medicine is likely, in many ways to be salutary, is the belief of Lindsay. He says that it will certainly tend to breadth of view, to a philosophic appraisement of the factors with which we have

to deal, to a recognition of the great underlying laws and secular processes which are related to our art. It may, perhaps, act as a damper on enthusiasm when it is realized that evolutionary change is slow and only partially under control; but, if this be the truth, it is better to know and recognize it. Medicine will gain in stability and in influence, as well as in dignity, by being in close relation with the higher thought of the day. In some not unimportant particulars it may react on that thought. Disease becomes something more than a disagreeable and embarrassing fact when we realize how closely it is related to evolutionary processes, how vivid is the light it is capable of throwing on evolutionary law. It takes its place—temporary we may hope—in the eternal order.

5. **Tubercle in Bombay.**—From a number of observations of cases of phthisis under his own care for the last ten years, Row claims that when a patient shows any improvement, side by side with his clinical progress, one finds in his sputum characteristic changes in the tubercle bacilli, especially in the grouping, and making allowances for all the fallacies connected with the technic of preparing the specimens under exactly identical conditions, one cannot resist being struck with the constancy of these changes, which, stated in brief, are:

1. Characteristic grouping of the tubercle bacillus—instead of being diffuse and scattered, or at best in twos and threes, they group in masses of eight, ten, twelve or more bacilli, scattered here and there in the specimen coming under focus as the search is proceeded with—in addition to the singles, twos and threes, which appear to be fewer. 2. A gradual diminution of the number of the bacilli found in the sputum. 3. A morphologic change of the individual bacilli—the individual rods, which were at first solid, show more beading, erosion of edges, and thinning—an appearance of distinct degenerative change in the bacilli. 4. A very great diminution of even these degenerate bacilli, so that one observes a few granules here and there indicative of some bacilli or their products. 5. Loss of their virulence, as no result is obtained by inoculation experiments. Thus it appears that in the course of infection there is always a certain phase when agglutinins make their appearance, and these agglutinins are manifested by the groupings above referred to, and, *a priori*, Row was led to suspect the possible presence of these bodies or allied bodies in the tuberculous sputum, in the spleen, and the liver, where the partial caseating necrotic masses were so prominently noticed in guinea-pigs. The splenic and hepatic lesions above referred to appear to be formed as though by selection, the whole defensive machinery of the guinea-pigs being brought into activity mainly in these organs, where the poison and its reaction products, so to say, become concentrated during the course of infection. These considerations have led Row to attempt to isolate from these foci a material which, when acted on by blood serum of undoubtedly tuberculous patients, would in all probability demonstrate the presence of agglutinins. With this object in view, extracts were obtained (1) from tuberculous sputum, (2) caseating glands, (3) necrotic and partially caseous livers, and (4) caseating spleens of guinea-pigs; and from the large number of chemicals tried alcohol has been selected as being the best reagent for the purpose. After a series of trials, the extracts of the first three classes were rejected as being unsuited for the purpose in view, because a large admixture of substance other than the active body in question are taken up by the spirit, and these other bodies, especially fats, extractives, and possibly traces of albumose interfere with the reaction; caseating spleens afford the best extract, especially those spleens which show a maximum of caseating material and a minimum of true splenic structure. Although the general result of the serum reaction in cases of tubercle is positive, yet when using the splenic extract, Row has tested the value of the reaction by its giving negative results with malaria, enteric infection, dysentery, meningitis, bronchitis, and a few other septic conditions. Fuller details and the important bearings of these actions in the study of allied diseases are reserved for a further communication.

6. **Tuberculin Reactions in Skin and Eye.**—A series of 153 cases were tested by McNeil as to the skin reaction in the group of diseases of bone, lymphatic glands and joints. The reactions were very clear, either emphatically positive or negative. A large proportion of the cases of enlarged or suppurating neck glands gave positive reactions. The test was of great value in obscure joint conditions where the clinical diagnosis was doubtful, and especially in cases of slight but persistent joint disablement after injury. Perhaps the most significant group is that of the simple pleural effusions. Thirteen out of 14 cases gave a positive reaction. Of the cases of tuberculous peritonitis, three failed to react. They were all severe cases with great general prostration, and two of them have already proved fatal. The groups of tuberculous meningitis and general tuberculosis illustrate well how in very severe or general infections the test, like the ocular reaction, breaks down. Of the skin conditions, two were clinically tuberculous—lupus and tuberculous ulceration—and gave positive reactions. The remaining negative results were in cases of eczema. Numerous control cases taken from cases of lobar pneumonia, empyema, chorea, and other miscellaneous conditions, were all negative, with one exception.

In 78 cases the Calmette and v. Pirquet reactions were tried in the same patient. The v. Pirquet test was positive in 31 cases, it was negative in 47. In these 47 negatives the Calmette reaction was also negative in every case. It was positive in 21 of the cases in which the v. Pirquet was positive, but it failed to react in the remaining 10 cases in which v. Pirquet was positive. That is to say, out of a total of 78 cases, the Calmette test either coincided with the v. Pirquet, or contradicted it negatively. It did not contradict positively in a single case—that is, it never gave a positive reaction where the v. Pirquet was negative.

10. **Oxaluria.**—Maguire is convinced that he succeeded in dissolving an oxalate calculus while existent in the higher urinary passages of a patient, and with removal of all the consequent symptoms. The patient, aged 44, passed through a period of great overwork, anxiety, and sleeplessness, and in consequence suffered from what he called "nervous dyspepsia." A year later, he placed himself under the care of a physician, who treated his dyspepsia, and later discovered a pronounced oxaluria—then, it is said, in the form of a dumbbell deposit. Subsequent hematuria and severe pain in the right flank, extending to the right testicle, made it probable that a calculus had formed in the upper urinary passages of the right side, but several *x*-ray examinations failed to demonstrate this. The patient was advised to take alkaline waters and a diet mostly composed of vegetables. Toward the end of three weeks he passed a small stone which proved to be composed of oxalate of calcium, but his local symptoms were in no way relieved, his dyspepsia persisted and his general weakness, ill-health and loss of weight had increased.

It was then that Maguire saw the man. He made a diagnosis of (a) oxaluria from excessive production of calcium oxalate, this in turn being the result of disordered metabolism caused by the dyspepsia; and (b) an oxalate of calcium calculus, lodged in the right ureter. He prescribed absolute rest, as nearly as possible in the open air, with a liberal diet of white meat, two or three times a week, a little champagne, and a medicinal course of dilute nitric acid and strychnin with digestive ferments at the beginning of each meal. An aloes and nux vomica pill each night and a dose of Carlsbad salts once a week were ordered to regulate the bowels. The symptoms, apart from those of calculus, very soon lessened in severity. The symptoms of stone, however, were as severe as before. It therefore seemed to Maguire feasible that if one could increase the acid phosphate of sodium in the urine by giving large quantities of the salt by the mouth, one might possibly at least dissolve off some of the spikes of the oxalate calculus and so facilitate its passage. Maguire then ordered, at first, half an ounce, then one ounce, and very soon two ounces of acid phosphate of soda, to be dissolvel in 100 ounces of distilled water and the solution drunk at frequent intervals during the twenty-four hours, but, so far as possible, remote from meal times. For half an hour or so after each dose there was considerable uneasiness in the abdomen, mostly from flatulence and a feeling of distention, but a little essence of ginger added to the solution relieved this to some extent, and it was never unbearable considering the end in view. The acidity of the urine increased about half an hour after taking each dose and the small amount of calcium oxalate still being deposited seemed always to be diminished in the urine passed at this time. The oxalate deposit disappeared entirely in about ten days. The blood in the urine gradually diminished and disappeared in about three weeks. The pain lessened gradually, but in six weeks there was no sign or symptom of stone; the patient could walk from ten to twelve miles and take severe gymnastic exercise without the slightest discomfort, nothing abnormal could be detected by the rectum, and the man felt well and in his usual spirits.

12. **Starch Digestion in Babies.**—A diastasic ferment is secreted by the salivary glands and pancreas of new-born infants and even before birth. Its amount and activity are slight in the first few weeks of life and after that rapidly increase. The glands, notably the pancreas, can be trained by means of a starch diet to the secretion of an increased amount of the amylolytic ferment. There is no inherent reason why this training should not be begun shortly after birth in the case of the bottle-fed infants instead of waiting until the child has attained the age of six months, as so commonly advised on purely theoretical grounds. Practical experience has shown that the usual barley water contains about 2 per cent. of starch. If mixed with an equal quantity of milk there will be only 1 per cent. of starch in the mixture. Such an amount is non-injurious and almost certainly is beneficial, as it encourages the growth of lactic acid. These organisms are of undoubted advantage in the prevention of the growth of proteolytic bacteria.

If a starchy food is used in the first two weeks of life it is advisable to begin with a milk mixture which will not contain more than 0.5 per cent. of starch and to gradually increase the amount as the child grows older. Indeed, at any age when a starchy food is first given it should be in very weak solution and slowly strengthened up to as much as 3 to 5 per cent. If the stools become very acid or if they give a distinct starch reaction, the percentage of starch in the diet must be reduced. Special care must be paid to these considerations in the first two months of life because of the deficiency of salivary secretion. Further investigations may possibly show that this is a point of little importance as the pancreatic secretion may be sufficient in quantity and activity. The evil effects of starch in early life are due to (a) excess; (b) its administration in the form of a more or less insoluble emulsion instead of a soluble food; and (c) the substitution of starch for the necessary protein, fats and salts. In other words, the mischief results from deficiency of necessary proximate principles of diet rather than from the presence of starch.

13. **Lung Puncture.**—In actual practice, a diagnostic puncture of the lung, according to Horder, may be made under two conditions: (1) if a pleural effusion is suspected and the result of the puncture negatives this; or (2) if no fluid is suspected in the pleural sac, but the lung is deliberately punctured for the express purpose of discovering the nature of a disease process within the lung itself. The material obtained is no less valuable in the first than in the second of these two conditions. The indications for lung puncture will vary somewhat with the desire of the physician for accurate knowledge with regard to the condition of the patient. In brief, it may be said that the puncture is indicated: 1. In any case yielding signs of consolidation of the lung, in which careful examination of the sputum fails to reveal the nature of the disease. It is, perhaps, pushing the value of "ocular demonstration" rather far to say that the lung puncture is indicated in a straightforward case of lobar pneumonia, even when there is no sputum for examination. But it should certainly be undertaken in any such case if the desired clinical course is departed from in any way to the prejudice of the patient. The puncture will frequently reveal the existence of a mixed infection (e. g., *B. influenzæ* and pneumococcus) when this is not suspected. 2. In abscess it is useful to obtain a specimen of pus from the actual seat of suppuration, for thereby a knowledge of the causal microbe is gained, often a matter of great difficulty or impossibility when dealing with the sputum. 3. In bronchiectases the same comments holds. The mode of performing the puncture follows exactly that of exploration of the pleura. Horder has punctured the lung for diagnostic purposes in some 14 cases. He suggests that it may possibly be found of service in suspected cases of acute pulmonary tuberculosis, in which condition sputum is so commonly absent.

14. **Dyspepsia of Old Age.**—Fenwick's investigations seem to indicate that out of every 100 cases of chronic dyspepsia in persons over 65 years of age, 66 are secondary to organic diseases of some important organ of the body, while the remaining 34 owe their symptoms to a progressive degeneration of the secretory structures of the stomach and intestines. In the former class the disorder of digestion usually takes the form of a chronic gastritis due to disease of the kidneys, prostate, heart, lungs, liver, pancreas, chronic gout or inefficient mastication, while in about 7 of the 66 cases, or in 10.6 per cent. of the entire number, long-continued hypersecretion, due to chronic ulcer in the vicinity of the pylorus, gall-stones, or diseased appendix is the cause of the constant indigestion.

18. **Intestinal Obstruction.**—The first case reported by Morison was one of intestinal obstruction due to a malignant stricture in the splenic flexure of the colon with hypertrophy and distention of the cecum and colon, proximal to the stricture, the contents being actively virulent in consequence of colitis and retention above it. No material benefit followed medical treatment. Following a preliminary cecostomy, half of the transverse and descending colon with a corresponding portion of mesentery was excised with the growth, the ends of the bowel were closed by sutures, and a large lateral anastomosis was established by sutures between the remains of the transverse and descending colon. Fourteen days later, after free irrigation of the colon, the cecostomy opening was closed and twelve days later the patient left the infirmary with his wounds healing and feeling well. The second case was one of acute intestinal obstruction from blocking of the small intestine, with strangulation of a considerable area of the gut. The obstruction was caused by something fixing acutely and kinking the ileum on the outer side of the cecum and ascending colon, and on separating this adhesion pus escaped. After cleaning away the pus, a gangrenous perforated appendix was turned out of the abscess cavity and excised. Recovery was subsequently uninterrupted.

36 *[illegible] of Hypophysis Tumor in Case of Acromegaly. P. Lecène.
37 Anatomy of the Wrist. (La région cubitale du poignet.) L. Bruandet.

35. Tuberculous Process in Tendon Sheath.—A domestic in a family in which there was a consumptive cut her thumb with a table knife and a process developed in the wrist with specific tuberculous lesions accompanying the connective-tissue reaction of an apparent myeloma. Recent research has demonstrated that a number of connective-tissue reactions, whose structure simulates that of certain tumors, are in reality tuberculous lesions. Gougerot has recently demonstrated this for a lymphadenoma, a lymphosarcoid, a fibroma and a spindle-celled sarcoma, although the bacteriologic proof is still lacking in some.

36. Hypophysis Tumor.—Lecène's patient was a man of 38, presenting the clinical picture of typical acromegaly, with epileptiform manifestations and impaired vision. A tumor was found in the hypophysis and was apparently successfully removed, but sudden fatal collapse occurred on the thirty-sixth day after the transsphenoidal operation.

39 The Leucocytes in Disease. (Vitalité, résistance et activité des globules blancs dans les maladies.) C. Achard.

38. Albuminuria as Symptom of Meningeal Hemorrhage.—In the case described, a woman of 54 experienced sudden malaise with general chilliness and severe headache, but no loss of consciousness, merely some torpor. In the liter and a half of urine voided during the twenty-four hours, 20 gm. of albumin per liter were found, but there was no tendency to edema or *bruit de galop*, although there was slight fever. Lumbar puncture revealed a typical and abundant meningeal hemorrhage; all the symptoms gradually subsided and by the ninth day there was no trace of albuminuria. In none of the similar cases on record was the amount of albumin over half this proportion. The discovery of large amounts of albumin in the urine without other signs of nephritis may aid in the differentiation of meningeal hemorrhage. In a second case Guillain based the diagnosis on this sign alone, the autopsy confirming it.

44 *Vegetarian Diet of Japanese Monks. (Ueber die absolut vegetarische Ernährung japanischer Bonzen.) G. Yukawa.

41. Prevalence of Hypochlorhydria.—Kelling expatiates on the necessity for collecting statistics in regard to the prevalence of conditions in the stomach connected with the absence of free and combined hydrochloric acid, and presents the findings in this respect in 4,937 cases of various stomach affections as his contribution to the subject. The list includes 192 men and 189 women with unquestioned ulcer, and 3,147 with stomach disturbances on a basis of neurasthenia or anemia: 1,729 men with hydrochloric acid and 395 without, and 900 women with and 216 without. Out of the 3,147 in the second group, 16.5 per cent. had no free hydrochloric acid in the stomach after the Ewald-Boas test breakfast—every seventh man and every fifth woman. In the 622 cases of gastric carcinoma, no hydrochloric acid was found in 462, while one in each four had free acid. These findings in regard to the acidity did not seem to be in any way proportional to the size of the cancer. He has encountered only two instances of chronic gastritis with ultimate gastric cancer, and thinks that chronic atrophic gastritis can be said almost to exclude cancer, while a peptic ulcer invites it. In 8 cases of pernicious anemia, none of the patients had free acid, but one had a small gastric carcinoma. These findings have confirmed him in the view that pernicious anemia, like leucemia, belongs in the group of tumor diseases, the essential trouble being a proliferation of erythroblast-forming cells. In 254 cases of gall-stone trouble, 30 per cent. of the patients had no free acid. This frequent lack of acid with gall-stones throws light on the cases in which lactic acid is found but no cancer. The lack of hydrochloric acid and the stagnation of stomach content favor the production of lactic acid as the duodenum is compressed by inflammatory processes around the gall-bladder. In 36 cases of gout and kidney stones, no free acid was detected in 33 per cent., and none in 38 per cent. of 21 diabetics, in 40 per cent. of 195 cases of tuberculosis and in 22 per cent. of 119 cases of typical migraine. Hydrochloric acid was found in all but 3 of 21 cases of mild chronic nephritis, and in all but 12 of 60 cases of old syphilitic infection. No special influence from helminths was discernible except with tenia, the figures showing a slightly larger proportion of hypochlorhydria among those who had had a tenia; it is possible, he suggests, that subacidity predisposes to lodgment of a tenia. The above data seem to indicate that in certain infectious diseases, such as tuberculosis, in cancer and in metabolic affections, certain toxins circulating in the blood have an injurious action on the glands of the stomach, which also seems to be the case with gall-stone disturbances. In regard to neurasthenic hypochlorhydria, he is inclined to accept the nervous weakness as responsible for the stomach disturbances by the resulting disturbances in molecular change and the consequent abnormal metabolic products. It is noteworthy that many of these patients suffer most from their stomach when they are especially fatigued. It is possible that the fatigue products circulating in the blood irritate the glands of the stomach. The irritation stimulates a healthy gland to increased functioning and hypertrophy, but it injures and finally destroys a congenitally weak gland. Hyperacidity and hypoacidity may thus proceed from the same cause, and the former may blend into the latter as the glands become exhausted. Many of these patients with hypoacidity are benefited by sodium, probably from suggestion, as they remember former days when sodium bicarbonate did relieve. These cases confirm the saying that gastric achylia cannot be diagnosed from the patient's complaints; the stomach contents must be directly examined. He was unable to discover any characteristic nervous symptoms for congenital weakness of the glands of the stomach. Collection of regional statistics in regard to hypochlorhydria may throw more light on the subject. He remarks that the only contraindications to the use of the stomach tube are aneurism of the aorta, extensive gastric hemorrhage less than three weeks before, and varices in the esophagus such as frequently accompany cirrhosis of the liver. These varices bleed readily, and consequently he never introduces the stomach tube without previously carefully investigating the heart and liver.

44. Vegetarian Diet of Japanese Monks.—Yukawa gives sixty-five tables of the various metabolic findings in a number of Japanese vegetarians, especially 12 monks who abstain from a flesh diet in any form. Over 46 per cent. of 200 elderly persons examined were found to have subsisted for decades and were apparently thriving on an exclusively vegetable diet, mainly rice. The average Japanese diet in the groups of farmers examined represented 2,877 calories or 55.6 calories per kilogram. The 12 priests, the subjects of the special metabolic research, had been living a cloistered life for from 15 to 55 years. Their diet represented merely 1,766 calories or 36.92 calories per kilogram. All were healthy and strong.

55 Diagnosis and Treatment of Incipient Tuberculosis. A. v. Sokolowski. Commenced in No. 42.

49. **Transillumination of Eye by Way of the Throat.**—Hertzell says that when there is any tendency to opacity in the lens it is difficult to inspect the fundus of the eye from without, but, with the light at the back, a clear oversight is obtained. The difference is as great as between trying to look from the street through a lace curtain into a room during the day and at night after the room is lighted up.

50. **Painful Cystitis.**—Posner declares that there is generally ulceration in every case of painful cystitis, the conditions in many cases being remarkably like those of round gastric ulcer. The pain in the majority of cases is due to ulcer, tuberculosis or tumor, and treatment varies for each. In the tuberculous form, a primary kidney process is probably the source of the bladder trouble, but whether this is the case or not, general measures should be instituted, including prudent general tuberculin treatment. There is no form of local treatment of a tuberculous bladder process that does not aggravate the disturbances. In the painful variety, the bladder will not tolerate even the ordinary technic of copious irrigation. The organ is actually a contracted bladder by this time, and has a capacity of only a few cubic centimeters. A cystitis which becomes aggravated under treatment with silver nitrate, instead of showing a change for the better, is strongly suggestive of tuberculosis. Corrosive sublimate may have a favorable action and use of small amounts of a 6 per cent. solution of carbolic acid have been recommended by Rovsing and is justifiable as a last resource. A mere incision into the bladder may have a favorable influence in some cases. The conditions for treatment are a little better with non-tuberculous ulceration; silver nitrate instillations may induce a complete cure if applied directly to the lesion with the aid of the cystoscope. Radical removal of the ulceration may be considered unless the lesion has progressed to an actual contracted kidney. In case of inoperable tumor, relief may be obtained sometimes from injection into the bladder of warm olive oil. If mineral waters are permitted they should be restricted to small amounts. Physical and dietetic measures are of the utmost importance, especially local application of heat, long sitz baths and avoidance of condiments. Milk is the best beverage; it may be evaporated to half its volume to prevent too much diuretic action. Although bed rest is favorable, its advantages are usually counterbalanced by those of out-door freedom, eventually with the use of a urinal, and Posner pleads for technical improvement of the urinals in vogue as they have too many drawbacks at present.

51. **Horror as Cause of Industrial Accident.**—A miner was ordered to disinfect with lysol the putrefying corpse of a mate who had been crushed in the mine a few days before. The miner developed thereafter a condition of mental depression incapacitating him for work.

53. **Adrenalin an Antidote to Strychnin.**—In this communication from von Noorden's clinic at Vienna, Falta reports experimental research on guinea-pigs and rabbits in which injection of adrenalin seemed to neutralize completely several times the fatal dose of strychnin. This occurs whether the adrenalin and strychnin are mixed and injected together or injected at different points of the body, only in the latter case the adrenalin should be injected a minute before the other. The experiments on frogs demonstrated that the action of adrenalin as an antidote is not due to delay in absorption, but seems to be a biologic process of different nature. Experiments are now under way to determine whether it possesses the same powerful action as an antidote in respect to diphtheria and other toxins.

56 *End-Results of Nephrectomy in 100 Cases. (Ergebnisse einer Serie von 100 Nephrektomien.) H. Wildbolz.
57 Antiferment Treatment of Acute Suppurations. (Antifermentbehandlung akut eitriger Prozesse.) S. Stocker.

56. **Experiences with Nephrectomy.**—The kidney was removed on account of tuberculosis in 90 of the 100 nephrectomies reported by Widbolz. Once convinced of the integrity of the other kidney, he did not hesitate to remove the tuberculous organ even when the general condition was extremely bad, and the results were favorable. His mortality was 4 per cent., but only two of the chachectic patients succumbed, one to advanced myocarditis and the other to uremia, as the other kidney was involved in the tuberculous process; the contracted condition of the bladder had rendered functional tests impossible. Another patient succumbed to pulmonary embolism ten days after the nephrectomy, and a thrombus was found in the renal artery. The only other fatality was in a patient with paralytic ileus a week after nephrectomy for hypernephroma. The paralysis of the bowel may have been due to local trauma of the adjacent colon or to injury of the bowel from the pressure of the hard cushion pushed under the patient to raise the field of operation. He noticed that postoperative meteorism was more frequent when the patients had been purged with a single large dose of castor oil than when smaller amounts of some milder purgative had been given for three days before. He uses ether anesthesia. The ordinary iodoform application after an operation on the tuberculous knee in two patients with a simultaneous tuberculous process in one or both kidneys caused such disturbances that the patients rapidly succumbed to iodoform intoxication, although only a comparatively small amount of iodoform had been used. He has never had a mishap from trusting too implicitly to devices for intravesical segregation of the urine, but states that he knows of a neighboring surgeon who had four mishaps in one year from this cause. In two of the cases the mistake was not discovered until after the sound kidney instead of the diseased one had been removed. In the two other cases the kidney was incised before the contemplated removal, showing the mistake, and the other kidney was then removed with no further damage except the entirely useless incision in the sound organ. In one of Wildbolz' cases intravesical segregation had never given decisive information as to whether the evident renal tuberculosis was unilateral or bilateral. After eight years of the trouble, catheterization of the ureters showed that the process was confined to one kidney and nephrectomy was followed by complete recovery. As a rule the tuberculous process in the kidney causes no disturbance until the bladder becomes involved, but occasionally the kidney process may simulate colic from renal calculi. In two cases in his experience a tuberculous process in one kidney was associated with calculi in the other, the patients recovering after nephrectomy and pyelotomy of the remaining kidney. The tuberculous kidney process may also attract attention by symptoms suggesting appendicitis when the right kidney is involved. One of his cases is peculiarly instructive: For ten years the patient had suffered from frequent colic in the right kidney region; then catheterization of the ureters disclosed pyonephrosis of the left kidney, the right being

apparently normal. No tubercle bacilli were found. After removal of the diseased left kidney, found totally degenerated and with two stones in the pelvis, all disturbances ceased, including the right colics and the gastrointestinal disturbances which had persisted for years. In another case a kidney was found totally destroyed by a tuberculous process which had caused no disturbances whatever, the tumefied kidney being a casual discovery when the patient consulted a physician on account of sterility.

64. Non-Operative Measures to Facilitate Childbirth.—Samuel expatiates on the importance of various measures which may permit delivery without the necessity for operative intervention, otherwise apparently imperative. Besides the Walcher posture, which often proves effectual in enlarging the pelvic inlet, he advocates a position which enlarges the outlet and thus frequently renders operative delivery unnecessary. The woman squats, but the squatting is not symmetrical; the two thighs do not press equally on the abdomen. The woman sits almost on one heel, the foot resting on its toes, while the other foot is flat on the floor, both thighs being flexed and both knees. The hands clasp the knees, permitting a firm support to aid in straining. This position, he says, was recommended by A. F. A. King to correct transverse presentation by the thigh pressure on the abdomen. The thigh of the posterior foot presses low down on the head, forcing it from the iliac fossa into the pelvic brim, while the other thigh presses high up on the breech end of the fetus. (See The Journal, May 25, 1908, page 1809.) Samuel has found that this squatting posture has further a most effectual influence in enlarging the outlet of the pelvis while it contracts the inlet, and is thus a valuable aid to delivery when the head or breech is low in the pelvis. It not only enlarges the outlet but renders it possible for the woman to take better advantage of the labor contractions, while it has the additional effect of greatly reducing the pains of labor. When the head is low down the Kristeller manipulation may also prove useful; that is, pushing the head along over the floor of the pelvis during a labor contraction, with both hands on the fundus. Not until these measures have failed should operative intervention be considered. King states that if the woman is unable to squat, the thigh pressure on the abdomen can be obtained by manipulating the legs, artificially flexing the thighs in the position as if the patient were squatting.

72 [illegible] of the Injured in Industrial Accidents. [illegible] Therapie Unfallverletzter.) A. Bum.
73 * [illegible] Achylia. W. Jungerich.

70. Treatment of Laryngeal Catarrh.—Fein remarks that there is scarcely any other medical term which is so persistently misused as "laryngeal catarrh." Every sensation, hoarseness, increased secretion, etc., in the throat and an abnormal condition anywhere in the neck is called laryngeal catarrh and treated as such or borne with resignation as "catarrh" is popularly supposed to be incurable. It is often forgotten that the throat is the passageway for the secretions from the lungs, bronchi and trachea, and for the secretions from the nose, as also for the gases and fluids from the stomach. He reviews the different conditions from these various causes which are accepted as manifestations of laryngeal catarrh when in reality the source is remote. When the affection is demonstrated to be actually an acute catarrhal condition in the rear wall of the throat, if the symptoms are annoying scraps of ice may be placed on the back of the tongue, not swallowed. Hard and highly seasoned food should be avoided and the patient may sip occasionally a little tepid mucilaginous fluid. The throat may be sprayed with an emulsion of liquid petrolatum and acacia, to which a few drops of turpentine, eucalyptus or peppermint oil may be added with a little cocain or cherry laurel water in case there is much pain. As patients have so much confidence in gargles, he orders a 1 per cent. solution of potassium chlorate, with a wet compress around the neck at night, but for acute conditions denounces mechanical measures of any kind, especially the use of the camel's hair brush. In chronic catarrh the differentiation must be left to the specialist, but, once differentiated, the general practitioner can, as a rule, continue the treatment ordered.

73. Gastric Achylia and Cancer.—Jungerich presents evidence to show that there does not seem to be any connection between gastric achylia and cancer; the fear that the former prepares the soil for the latter is unfounded according to present testimony. In his own experience he has had thirty-two patients over the age of 40 with gastric achylia since 1899, some of them with a history of achylia for from twelve to thirty years, and yet cancer is not known except in two patients who succumbed to a cancer in the pancreas or sigmoid flexure. The other patients are still in comparatively good health and weight, the appetite good when the dietetic regulations are observed. He has also investigated the previous history in 50 cancer cases, all in private practice, and was unable to find any evidence speaking for the existence of gastric achylia before the first signs of the cancer became apparent. The malignant disease proved fatal in one or at most in two years. He presents in tabulated form the details of his group of 32 achylia patients who have been in his care at any time since 1899.

74. The Viscosity of the Blood.—Trumpp has been making a special study of the viscosity and proportion of hemoglobin and albumin in the blood of children. He examined the blood of 152 children and 7 parturients and of numerous animals in the slaughter-house. His article is a contribution to the infant science of "viscosimetry," which he thinks is destined to prove an important aid for diagnosis and prognosis and possibly a guide to treatment in certain affections. It is evidently an important factor in the solution of many scientific questions. The blood showed most viscosity in a new-born infant in blue asphyxia, 12; the lowest figures, 2.1, in a child with splenic anemia. The unusually high viscosity in the acute stage of alimentary intoxication attracted attention, the figures representing the viscosity growing smaller as the trouble was corrected. These findings confirm the concentration of the blood in alimentary intoxication which Reiss determined by the refractometer. The average viscosity of the blood in children is about 3.65; in infants from 3.2 to 3.6, and in healthy children between 7 and 13, the average is between 3.5 and 4.1. The average in adults, according to Hess, is 4.5. There did not seem to be any connection between the viscosity and the proportion of hemoglobin, but carbon dioxid increased the viscosity.

76. **Prevention of Postoperative Thrombosis.**—Mendel applies the term "thrombophilia" to a predisposition to formation of thrombi which some patients seem to display—the exact reverse of hemophilia. In one such case in his experience a previously healthy woman had phlebitis during the puerperium and since then has developed thrombophlebitis with every intercurrent infection since, once during influenza and once with simple tonsillitis. A tendency to eczema seems to accompany this thrombophilia. In another case thrombosis developed after a trauma of the foot and recurred during attacks of influenza and also in the inferior mesenteric vein during a catarrhal affection of the large intestine. After subsidence of the colics the stool contained traces of blood for weeks, but there were no objective findings otherwise except tenderness of the entire colon. The patient recovered gradually, but only 6 of the 60 similar cases on record terminated in recovery. The integrity of the heart and large vessels confirmed the non-existence of an embolus; the favorable outcome was probably due to the fact that the inferior instead of the superior mesenteric vein had been involved. These and other cases in his experience confirm the assumption of an infectious process in the wall as an indispensable factor in thrombosis. The thrombosis in these cases has generally been accepted as a casual complication of traumatic inflammation, but Mendel regards it as a sign of abnormal constitution of the blood which reacts to any local or general infection with the formation of thrombi. Interference with the circulation does not seem to be much of a factor in the thrombosis, but at the same time the limb should be raised to prevent extension of the process. Allowing patients to get up early after laparotomy or delivery will not prevent the development of thrombi in a predisposed venous system. No proof has been offered to date that thrombosis and embolism are less frequent when the patients are allowed to get up early. On the other hand, it must predispose to embolism especially when there is a tendency to abnormally rapid coagulation in the blood.

78. **General Anesthesia with Part of the Circulation Shut Off.**—Hörmann reports experiences with Klapp's method of damming the circulation described in The Journal, Oct. 19, 1907, p. 1408. Hörmann has applied this method in 50 cases. Much less of the anesthetic is required, he asserts; the patient rouses rapidly, while the blood that has been shut off, when released, serves as a fresh supply which stimulates the nerve-centers, warding off asphyxia by this autotransfusion in case of impending paralysis of the respiratory center. The only contraindications are varicose veins and arteriosclerosis. No by-effects were observed and the technic is the simplest possible, the aim is to shut off from the general circulation the blood already in the limbs. This is done by applying an Esmarch bandage just before the anesthesia is given. Only the amount of blood normally in the limb is thus dammed, without congestion or expulsion of any of it. The bandage must shut off the circulation completely. (The Journal mentioned experimental research confirming the theoretic and clinical data on which the method is based: Nov. 21, 1908, p. 1826, and Jan. 2, 1909, p. 84.) Hörmann compares in three tables the consumption of chloroform and ether in several series of operations showing that with the circulation thus sequestrated only about half as much of the chloroform was required as without it. He always makes a subcutaneous injection of 0.01 gm. morphin one hour before the operation. The chief advantage of the method, however, is that in case of threatening mishap from the anesthesia, by removing the bandage the fresh blood streams back and averts all danger of further trouble. As a rule, only 15 gm. of chloroform were needed, given rapidly at first and then followed with ether, an average of 55 gm. ether being required for major operations.

80. **Nephritis.**—Casper calls attention principally to two special forms of nephritis, a chronic hematuric variety without albumin, tube-casts, edema or other signs of disturbances in the circulation. Hemorrhage in one or the other kidney alternately seems to be the only trouble, the urine in the intervals, which may be months or years, being apparently normal. In the other variety the pathologic changes are so minute sometimes that they escape discovery at autopsy, but a circumscribed nephrosis is responsible for the hemorrhages. This condition is called by the French *"néphrite parcellaire,"* but, Casper asserts, it is certainly not a nephritis. In these cases the hemorrhage occurs always from the same kidney. It is generally more profuse and persistent than the above hematuric nephritis; clots collect in the bladder and may clog the outlet, the kidneys are not palpable or tender and the urine in the intervals is absolutely normal. The apparent similarity between these two affections with their single symptom, hemorrhage, is due only to the fact that the tests for examining the urine in hematuric nephritis have not been sufficiently delicate. More sensitive tests will reveal minute amounts of blood and tube-casts. The prognosis for both affections is good as a rule; it is extremely rare that the hemorrhage is so intense as to require an operation. Pain in the kidney due to nephritis is generally a dull ache, more pronounced after physical exertion and subsiding during rest. But nephritis may at times induce a typical colic though the urine is free from pathologic content. With stone colic red corpuscles are always to be found in it. After the attack has subsided, examination of the urine with sensitive tests (20 per cent. sulpho-salicylic acid), will reveal traces of nephritic albumin and tube-casts. This colic nephritis may be associated with the hematuric nephritis; the colic is the result of sudden edema of the kidney. In conclusion he expatiates on the good prognosis of chronic nephritis in many cases; the kidneys may become contracted in time but not until after several decades, during which the patient feels well. The vascular system, heart and blood-pressure behave as in normal conditions; the albuminuria is often a casual discovery. All this applies especially to the arteriosclerotic kidney; the patients may reach the age that their other vital organs allow. The atrophic process in the kidney corresponds merely to the normal changes with age in the other organs.

82. **Pregnancy Blindness.**—In Himmelheber's case a woman of 34, with chronic nephritis, in the fifth month of her seventh pregnancy developed amaurosis with headache and detachment of the retina on both sides. Abortion was induced and was followed by retrogression of the detachment of the retina, but the atrophy of the optic nerve proved irreparable. The trephining to relieve the pressure on the brain evidently came too late; the pupil reaction was abolished by the second day after the woman had entered the hospital. The case teaches the importance of emptying the uterus and of prompt measures to reduce the intracranial pressure if vision is not promptly restored.

96 Diagnosis, Localization and Treatment of Echinococcus Disease. (Die Echinokokkuskrankheit.) F. Colombani.

91. Serotherapy of Cholera.—This communication reports the experiences at St. Petersburg with Kraus' antitoxic cholera serum. It was administered in 54 cases and 55.5 per cent. of the patients died, but in all but 4 of the cases the disease was in its severest form. The mortality without the serum in a corresponding series of 224 equally severe cases was 84.3 per cent. Kernig mentions that intravenous saline infusion proved a valuable adjuvant and may have been partly responsible for the better results in the serum-treated patients, as it was only rarely applied in the other series.

95. Foreign Bodies in Upper Air Passages and Esophagus.—In this report from von Eiselsberg's clinic the advantages of prompt tracheotomy are extolled as liable to give better results, in the hands of the general practitioner, than tedious attempts at extraction by the natural route with the inevitable injury from them and the bleeding. Some instructive skiagraphs are given and the point emphasized that a foreign body in the esophagus generally entails the same dangers as an incarcerated hernia. If extraction is not promptly successful, an operation should follow without delay. In 11 cases reported in detail, the outcome was favorable in 9, recovery taking place in from two to seven weeks. One child who had swallowed a coin succumbed to pneumonia a week after the esophagotomy. The other fatality was in the case of a man of 41 who had swallowed two false teeth set on a plate. After attempts at extraction with fingers and induced vomiting had failed, a physician tried to push the set down into the stomach and apparently succeeded as a sponge held in a coin catcher was passed through into the stomach and the patient was able to eat bread and potatoes, the stomach tube could be introduced without effort and Roentgen screen examination was constantly negative, but the patient complained of pain in the chest and a hard sound introduced encountered an obstacle, although the soft stomach sound passed readily into the stomach. Esophagotomy over a week after the teeth had been swallowed finally resulted in their removal, but in loosening the impacted teeth the wall of the esophagus was perforated, and septic pleurisy followed, which was soon fatal. The practice at the clinic is to introduce a sound and examine with the esophagoscope and try to remove the foreign body if known to be round and not firmly fixed. But if the case is old and the foreign body has pointed edges or is firmly impacted, esophagotomy is done at once for fear of digging a groove in the wall of the organ as the article is drawn out. The food after the operation is given through a bougie and nothing but milk and tea by the tablespoonful is allowed for the first two days. The third day the bougie is removed and the tampon in the second week, and healing is usually complete by the end of the third week.

97 *Proper Moment to Commence the Operation Under the First Whiffs of Ether. (Erkennung des richtigen Momentes im Aetherrausche.) J. Landström.

97. Operating Under First Whiffs of Ether.—Landström keeps the operating room perfectly quiet and watches the patient's throat as the ether is given. As soon as the patient feels the fumes of ether salivation is induced and he swallows at brief, regular intervals. When the anesthesia is deep enough to suspend the swallowing reaction to the salivation, this is the right moment for the operation to begin. So Landström waits until the patient ceases to make the swallowing movements or the intervals become much longer, and then commences the operation without further tests of the patient's sensibility.

107. Septicemic Fevers.—This is the concluding article in the series in which Rummo has been discussing typhoid, paratyphoid, Malta fever, cryptogenic fever, colon bacillus infection, etc., which he groups together as polymorphous septicemic fevers and febrile conditions. They are the result not only of the action of the specific germs, but of their combinations or possibly their association with germs of different species. He denounces the conception of fever from autointoxication, saying that the importance of autoinfection and of the colon bacillus as the single factor in fevers has been much overestimated. The agglutinating reactions can be relied on in this septicemic group of fevers.

109. Latent Pneumonia.—Gentiti calls attention to latent pneumonia as the most dangerous form of this disease. The absence of râles, bronchial souffle, cough and expectoration, indicate a lack of resisting power against the diplococcus. In a case of this kind described, the patient was a man of 46, with a family history of tuberculosis and a long preceding tuberculous affection of the testicle requiring operative measures. The chill, pain in the right intercostal space, intense headache and high fever were not accompanied by any local signs of pneumonia for several days, but then slight expectoration followed and the pneumococcus was found in the sputum.

112 *Life Expectancy of Extra Hazardous Risks in Life Insurance. (Nogle Bemærkninger om Livsforsikringens "mindre gode Liv.") E. Salomonsen. Commenced in No. 38.

112. Ultimate Fate of Extra Hazardous Risks Among the Insured.—Salomonsen declares that the medical aspect of life-insurance is gradually working into a science, as the examiners are learning to estimate the "statistical prognosis" with as much accuracy as physicians now are able to estimate the clinical prognosis in a given case. Until recently the physician's interest in a case ceased when the patient had completely recovered. The surgeons introduced a revolution in this respect, as they found that they had to keep track of their patients to justify the expediency of their operative measures, proving in black and white that the life expectancy had been increased by their intervention. Physicians are now seeking to follow them in this line, trying to determine the influence on the life expectancy thereafter of the disease through which they have carried the patient and the influence the disease will have on the general resisting powers in later life. As a contribution to this subject he has been investigating the after-history of the candidates accepted with an extra rate by the Danmark, a Danish life-insurance company. He has thus sifted out 2,100 cases of extra-hazardous risks in going over the records of 30,000 insured between 1873 and 1906. His surprise was great when he found that the mortality among them was only 106 while the estimated mortality of a corresponding number of normal risks is 101.84. Another surprise was the discovery that the deaths were seldom due to the affection for which the insured had been rated as an extra risk. This has been shown in regard to hernia in the statistics from the German Gotha insurance company. Out of 3,104 persons with hernia insured, the hernia was responsible for the death in only 0.38 per cent. On the other hand, fatal incarcerated hernia caused the death of 0.2 per cent. who had no signs of hernia at the time of the medical examination. The mortality from syphilis is increasing among the syphilitics insured in the Scandinavian and other countries of Europe as it is now accepted as responsible for general paralysis. The statement by a medical examiner that the candidate has had syphilis but that it was mild and brief and consequently may be disregarded, is not endorsed by the companies now, as time has shown that general paralysis is most liable to develop in these mild cases owing to the lack of intensive treatment. In regard to tuberculosis, also, the general practitioner is liable to be more optimistic than is justified by the facts to date. The statistics from the sanatoriums, etc., include too few cases and extend over too few years to justify at present a favorable prognosis in regard to complete recovery after the disease has once been installed in one or both lungs. Some companies regard chronic otitis media as demanding an extra rate, but the mortality from this cause in the Danmark has been very low and in the Gotha company it was only 0.12 per cent. of 46,480 insured. The Danmark experiences with appendicitis confirm the assumption that the first attack is the dangerous one. None of the insured regarded as extra risks on account of preceding appendicitis died of appendicitis later; the deaths from it were all in persons free from a history of appendicitis. The Italian and Swiss companies have not suffered from losses with syphilitics so much as the Scandinavian, and he is inclined to accept the theory that this infection has become attenuated in these other countries where it is more prevalent, the population having become acclimated to it, as it were. He warns that in studying life-insurance statistics it must not be forgotten that the persons who drop out after keeping up their policies for a longer or shorter period are liable to prove misleading in drawing conclusions from the figures recorded. The Danmark statistics do not indicate that heredity has much influence on the development of cancer, but accurate knowledge on this point can be obtained only by study of the comparatively few who have been on the books for long series of years. He cites 15 cases of these extra-hazardous risks in which the dubious prognosis was confirmed by the death within a few years. In 6 in this group, a previous bronchitis or pneumonia had been followed by very protracted convalescence, several months elapsing before the men were able to resume work, but the physical findings were normal at the time of the medical examination for the company. In another case a man of 35 six years before had had a contusion of the chest followed by expectoration of a couple of teaspoonfuls of blood, but he soon recovered and had no trace of hemorrhage afterward. The breath sounds were a trifle diminished in intensity in the supraclavicular but not in the supraspinous fossa; otherwise the findings were normal. The examiner declared the man sound, but he died of consumption six years later. On the other hand, the records show numbers of insured apparently far more seriously handicapped who are still in good health. Salomonsen urges in conclusion that scientific study of the life expectancy after certain affections is liable to throw light on many other branches of medicine.

POPULAR EDUCATION AS A STIMULUS IN PUBLIC HEALTH WORK*

W. M. BRUMBY, M.D.
President of the Texas State Board of Health
AUSTIN, TEXAS

In this paper I have made no effort to treat the subject of public health administration exhaustively, nor have I referred extensively to methods in use by other hygienists of the present or the past. I have simply stated some conclusions, together with the data on which they are founded, and in a way this paper is like a case report, dealing with my own work.

I have long been of the opinion that there are two distinct aspects of state medicine. One of these is knowing the remedy to be applied, and the other is knowing how to get the people to apply the remedy. The first consideration I take for granted as a requisite possessed by every good sanitarian. The second consideration—how to get the people to apply the remedy—is the main theme of this paper.

There are men, and intelligent men, who believe that the sanitarian, having decided on what he believes is the wisest course, has nothing left to do but to sail that course, regardless of public opinion. The sanitarian is a specialist in his line. He knows better than the public what health measures are needed. It is a sacred obligation with him to act in accordance with what he knows to be right, let the people believe what they will. This view is the correct one whenever the sanitarian has authority and means necessary to carry his plans into execution. But there are many reforms needed in our country which are at present outside the authority of the health officers. To secure the authority and means to enact the needed reforms is the task of the sanitarian.

This brings us face to face with the question how the people can be induced to yield the authority and money for the purpose of combating the diseases which menace the public health. To meet this issue successfully the sanitarian must possess a certain degree of tact, political ability, or statesmanship—call it what you may. He must be able to divert a part of the sum total of political power invested in the people and guide it into certain channels.

In doing this the sanitarian does not deal with the populace directly, but with representatives of the people, public officers. These officers draw their powers from the rank and file of the citizens. While to a certain extent they are leaders, yet they are to a great extent followers of public opinion. Personally they are willing to do anything to help the cause of sanitation, but before "going on record" as favoring the establishment of an improved water-works system, for instance, they usually delay action until popular clamor makes itself heard in favor of the proposed reform.

Vox populi is *vox dei*. The sovereign people are the fountainhead of all authority in a free republic, and to get the authority, or the money, which is the sinews of war against disease, it is necessary to go to that fountainhead. If you stop short of the fountainhead, there is always some one else upstream from you who is diverting the current.

I have found that one most excellent method of reaching the people is through the newspapers. In the administration of almost any health officer, there occur events of great value as "news." In giving these news items to the press, it is well to sandwich in a miniature lecture on sanitation with each news item. Of course, if the tidbit of news is ballasted too heavily with scientific "dope," it will find the waste-basket. But in many cases, an interview from the health officer, telling "how it happened" is warmly welcomed by the press, even though the interview read like a primer on sanitation.

Next to his ubiquitousness the most characteristic thing about the average newspaper reporter is his skill in getting things wrong. This makes it necessary to prepare certain important interviews and hand them in already written to the newspapers. It is easy to overstep the line here and overlook the newspapers.

In newspaper work, as in every other branch of hygienic education, cooperation by different health officers and physicians is very important. Public meetings participated in by the lay and professional public are an excellent means of stimulating sanitation. The physician has by dint of hard labor become master of a certain amount of that divine attribute called knowledge. The public is hungry for this knowledge; people never fail to avail themselves of an opportunity to stand by and pick up the crumbs from a medical conversation. The public meeting offers the health officer an opportunity to dole out to them such store of his knowledge as they can digest and assimilate. To get best results it is absolutely necessary that no physicians should stand aloof and criticize. Therefore, careful organization is a prerequisite.

Closely related to these public meetings are the so-called traveling institutes of hygiene, as elaborated by my friend, Dr. Mayer, of Louisiana. The "tuberculosis exhibits" are all special phases of his original idea, which was promulgated years before the awakening on the subject of phthisis. The traveling exhibit, consisting of pictures, models, charts, figures, and other accessories are valuable because they stimulate interest and also because they make the subject-matter easier to grasp. Concrete facts are learned easily, and the eye aids the brain in learning the scientific data presented in one of these traveling institutes of hygiene. I am of the opinion that the typhoid fly should be included in these exhibits as well as the tuberculous cow. I think the vaccination problem should be explained and pictures bearing on it exhibited. In certain of the southern states the malarial mosquito should be explained. In short, I think that traveling exhibits are needed to teach the whole of sanitation and preventive medicine, as well as tuberculosis.

---

*Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In this connection it occurs to me that the state boards of health are in a position to aid the counties or cities by sending on request a lecturer and demonstrator with an exhibit. The peculiar quality of mind which leads the people to heed the advice of a stranger, where they ignore the words of their lifelong friends, is proverbial. For this reason the health officer of County A can go to County B and lecture with splendid results. Later, the health officer from County B, looked on as a commonplace man in his own county, can come into County A and preach sanitation with results as brilliant.

In a similar way, the U. S. Public Health and Marine-Hospital Service can materially assist each individual state in the battle for better public health. The surgeon who is an officer in this distinguished service enjoys a prestige and renown commensurate with the great corps to which he belongs. The public looks up to him. His words are heeded. Furthermore, his official position is a guarantee that he will be free from any local prejudice. The public does not suspect his motive. He is probably not even a resident of the state in which he may lecture, and may expect to leave that state immediately, possibly never to return. Under these circumstances his words have an unusual burden of meaning which make them productive of much good. I then would call your attention to the fact that cooperation between county and state, and between state and nation, is essential to the best interests of public health.

In conclusion, I desire to refer to one phase of public health administration which frequently causes embarrassment, especially in the southern and western states. I refer to the fact that many of our public health officers are engaged in the private practice of medicine. This is at present a widespread condition, and one that is as natural as for water to run down hill. But it very seriously hampers the cause of public health. The health officer may be entirely conscientious and I take it for granted that he is, and that he does his work thoroughly. The fact remains, however, that his competing fellow practitioners of medicine look askance at any public utterances which he may make. The "publicity side" offends them. They want him to keep himself in the background. Now, no health officer can do his duty without appearing in the lime-light from time to time. Hence he is driven to do one of two things—either offend his fellow practitioners by coming out in the open, or compromise his conscience by lying low and letting things drift. He has no choice between the two. The only logical result will be in the end that health officers will be paid to do their work, so they will not have to do practice on the side to gain a livelihood. We should work toward that end, remembering that for the present we must do the best we can with the means at our disposal.

ABSTRACT OF DISCUSSION

Dr. William Porter, St. Louis: The education of the people underlies all activity and organization in this work. People must know. Once having knowledge they will support that which touches their lives and homes and happiness. It is well, it is necessary, to have men fitted to give this instruction, and these men or others should be ready to direct the growth and movement which will surely come in the wake of public instruction. In the masses, even in the most ignorant parts of our cities, where crowded, congested living is most pitiable, is a latent force which once aroused is potent for good, and for progress. In St. Louis is a man whose home and early life was in the worst ward of the city. His associations were bad; he grew up thoughtless and careless; his name was synonym for leadership among the worst classes. Slowly but surely the desire came to him to do something for his associates. In so doing he lifted himself. He saw a great light—to-day he is an honored state senator, one of the best helpers we have in all that pertains to the uplift of the needy and the limitation of disease. It is such influences as these, resulting from years of educational work in the field, that has given to Missouri its present beautiful sanatorium for incipient tuberculosis with its half a million appropriation; has given it the Commission on Tuberculosis with its $125,000 for five years' further educational work, and has entered the penitentiary with an investigating committee and aids in the segregation of convicts.

We of Missouri are often asked why our people are so liberal to these causes. It is simply the harvest of the seed that has been patiently sown. We are fortunate in that our governor and the mayor of St. Louis are with us, but back of these are the masses—the people on whom we can depend. I urge the use of the newspaper under proper surveillance, the public lecture, and the instruction of the school children by illustration and text-book. The former is an important but delicate matter; the latter is best of all for future results. Every child should have access to lectures and exhibits and carry into the home a well-prepared leaflet with simple notations. Five hundred thousand of these have been carried into St. Louis homes by the children of public and parochial schools.

Dr. Juan Guiteras, Havana, Cuba: There does not appear to be any sustained effort made throughout the South to impress on the people the lessons of experience in the matter of antimosquito campaigns for the prevention of yellow fever and malaria. The cities of the South, I am sorry to say, are still trusting solely to methods of quarantine that have been proved in the past, on many occasions, to be inadequate. Unfortunately, the great object lesson offered by Cuba has not been brought clearly before the people; on the contrary, in some quarters an effort has been made to obscure it. The success of Cuba in keeping down and within reasonable limitations the recent visitation of yellow fever in that country, has not been appreciated in the proper spirit by our neighbors of the southern states. During three years of our recent visitation (1905-1908) we had nowhere the widespread epidemic manifestations that characterized the days of the Spanish domination there, or of the recent outbreaks of Laredo, New Orleans and Pensacola. The reasons for this difference are two: First, we have never hesitated a moment in announcing the first appearance of the disease, and in taking frankly and openly the necessary step towards preventing its propagation. The press, throughout the South, did not, as a rule, endeavor to show the advantages of such a procedure. On the contrary, the impression was created, with a degree of unfairness which was very unpleasant at times, that the cases were being discovered and made public by state and United States medical representatives in Cuba. The people of the South were usually informed by cable in words to this effect: "The representative of the State Board of Louisiana in Cuba reports three cases of yellow fever to-day in Havana;" or another officer would cable: "I found a case of yellow fever to-day at Las Animas Hospital," and so forth. Now, as a matter of fact, the cases were invariably discovered, shown, and reported by the Cuban sanitary authorities, who were most anxious to demonstrate what they considered an essential part of their successful method of controlling the disease. To report the facts otherwise was unfair to Cuba, and it was most unfair to the people of the South who lost thereby the educational advantages that they should have derived from the contemplation of a successful campaign on the basis of a prompt declaration. The second reason of the difference in the results obtained is the maintenance of a persistent and continued fight against the stegomyia. I am afraid that little or nothing is being done in this direction throughout the South.

MEDICAL SUPERVISION OF ATHLETICS AMONG BOYS AT BOARDING SCHOOL[*]

NATHANIEL BOWDITCH POTTER, M.D.
NEW YORK
AND
JAMES TAYLOR HARRINGTON, M.D.
SUMMIT, N. J.

Several years ago a boy of 15 was brought to one of us with a markedly dilated heart. For some weeks he had been running a mile nearly every afternoon at one of the best-known boarding schools in New England. Since then, among others, a boy with pulmonary tuberculosis, another with so-called physiologic albuminuria, another with leukemia, a fourth with pronounced cardiac insufficiency and much overgrown, from four different and all excellent boarding schools, have been brought to the attention of one of us, and in none of them had their condition been recognized or properly studied. The observation of these cases stimulated this preliminary study of selected boys before and after exercise at a number of boarding-schools.

We first examined 38 boys, 36 of them from five boarding schools, two in Connecticut, two in New York and one in New Jersey; and 2 of the boys from a day school in New York City. After examination each boy ran a mile at his own pace, was re-examined immediately on finishing the run, and in most instances a third time, from one-half to three-quarters of an hour later. The accompanying table shows the results of our examinations.

The method followed in each case was, first, to count the pulse and to estimate the systolic blood-pressure in the vertical posture; then to determine in the horizontal posture whether there existed any increase of cardiac dulness, the relations of the pulmonic and aortic second sounds, the presence of apical or basal murmurs and the existence of a thrill; and, while the boy was still in the recumbent posture, to count the pulse again and to estimate the systolic blood-pressure. The first specimen of urine was passed by each boy just before the run and, with the exception of the nine boys at School A, the second specimen was passed during the time of the third examination, one-half to three-quarters of an hour after the exercise. In School A a period of about two hours elapsed after the exercise before the second specimens were voided. These specimens were all examined as freshly as possible by Dr. Wilson G. Wood, to whom our thanks are due. He, of course, knew no details of our physical examination.

Selection of Boys.—At each school an effort was made to select half the number from boys especially vigorous, athletic, muscular and well developed, and the other half from boys who had grown considerably especially in height during the past two years. This effort was only partially successful.

Selection of Exercise.—It was found impossible to examine boys before and after a contest. One of us made this attempt at a dual meet between two schools but failed. The interest was centered elsewhere and the noise and confusion rendered examination impracticable. We chose a mile run as being a good test of strength and endurance for boys of this age, able to participate in football, hockey, basket-ball, track athletics, rowing and baseball. Each boy was told to take his own time and not to overexert himself, but to finish his run reasonably strong. There was no competition, although the boys were interested and some of them surprised at the time they made. Generally speaking, the most athletic of the boys made the best time and usually showed the least effect of the exertion.

We wish to call especial attention to some of the features of the examination in the following:

School A.—Nine boys training for the crew were selected. After examination each boy ran a mile at his own speed. No. 4, aged 18, one of the best oarsmen and said to be the hardest worker, exhibited a reverse blood-pressure,[1] an enlarged heart both to the right and left, a loud systolic murmur at the apex and base, an accentuated pulmonic second sound, and a slight thrill at the apex. His urine, voided after exercise, showed a marked trace of albumin, and casts were detected in both specimens. The boy stated that he tasted blood during the run, and that this was a usual occurrence with him during or after hard exercise. Two other boys exhibited casts in both specimens. Three other boys exhibited albumin in both specimens.

School B.—Nine boys were selected as well as possible according to the plan specified above. No. 17, aged 19, the best runner in the school, who recently broke the school record for a mile, ran his mile easily and in good time. He exhibited an enlarged heart both to the right and the left, a heaving apex-beat, a systolic murmur at the apex and base, and an accentuated pulmonic second sound. His urine, voided after the run, showed a marked trace of albumin.

No. 11, aged 19, a large, muscular, strong boy, was said to have injured his heart playing football two years before. He showed a reverse blood-pressure, a slight emphysema, a slight increase of cardiac dulness to the left, a systolic murmur at the apex and an accentuated pulmonic second sound. His urine, voided after exercise, exhibited a faint trace of albumin.

No. 10, aged 17, a tall, slight boy, who had grown four inches in the past year, had been compelled during the winter to enter a lower form. He has had digestive disturbances, some circulatory weakness and several attacks of furunculosis during the past two years. He exhibited a reverse blood-pressure; his pulse before exercise was 118 in the vertical posture and 96 in the horizontal; after exercise, 152 and 124. His cardiac dulness was diminished, and he was exhausted after the exercise. Albumin and casts were found in both specimens of urine.

School C.—Eight boys were selected at random. No. 20, aged 17½, was a large, well-developed boy, had ruptured a vessel in the sclera of one eye a few days before while wrestling. He exhibited a high blood-pressure, vertical 175 mm., horizontal 150 mm., before exercise. His heart was enlarged, there was a loud systolic murmur at apex and base, and an accentuated pulmonic second sound. Both albumin and casts were present in the urine voided after the run.

School D.—Seven boys were selected from those who were training for track athletics; all of them showed albumin, and three of them casts, in the specimens of urine passed after the exercise.

No. 30, aged 15, a tall boy with remarkably well-developed legs and thighs, had grown decidedly during the past year. His pulse was 180 after the run. His blood-pressure was rather high before and rather low after the exercise. His urine contained albumin and casts in both specimens, and in the one voided after the run the albumin was a heavy trace and the casts were in great abundance.

---

[*] Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

[1] This method of testing the blood pressure was suggested to us by Dr. George L. Meylan, Adjunct Professor of Physical Education, Columbia University. The existence of what we have termed a "*reverse blood-pressure*," i. e. a higher blood-pressure in the horizontal than the vertical posture, he tells us, has often suggested some circulatory weakness which seems wise to supervise by repeated examination before a student is allowed to compete for a position on some college team.

In addition to these thirty-eight boys, six boys at School G in Massachusetts were examined before and after a quarter-mile run, the results of which are summarized in Table 2.

One of these boys, at the age of 13, exercised unduly the first year he passed at this school and was found to have a dilated heart when he returned home on a vacation. Our examination, made at the age of 19, showed slight thickening of the arteries, slight cyanotic color, an enlarged heart, a loud systolic murmur at the base, and an accentuated pulmonic second sound.

Eight boys were examined at School H in Massachusetts, before a one and a half mile practice row, and four of them after the row. Two exhibited a reverse blood-pressure. Albumin was found in all four specimens of urine voided after exercise; the sediments were not examined because the urine had decomposed. One of these four boys showed after the row, in addition to the reverse blood-pressure, a moderate cardiac dilatation and slight evidence of exhaustion.

Six of the Columbia freshman crew, ages 16 to 22, average 18½, were examined before and after a light practice row. The blood-pressure was reversed in three

Indican: No marked excess was found in any specimen. Acetone: No acetone found in any specimen.

50 per cent. One of these three, who had been under Dr. Meylan's observation on account of a rapid pulse persisting after an attack of influenza in February, showed in the examination of urine after the row a heavy cloud of albumin and many casts. Another, aged 19, had grown markedly in the past year. The examination of the urine, both before and after, showed a trace of albumin and many casts in the specimen after the exercise. Another of these, aged 18, was the only one who showed any evidence of fatigue after the light row. He exhibited some emphysema. He had played water polo hard during the winter. There was a cloud of albumin and casts in the specimen taken after the exercise.

Ten Marathon runners were examined after the race, and all except one exhibited a low blood-pressure; 90 to 100 mm. The exception, the winner, showed 160 after and 120 before. Three were examined before and after another race. In the examination afterward all showed a blood-pressure below 105, while in that made before all showed a blood-pressure above 140.

These examinations show that some of the boys should not be allowed to take part in strenuous exercises or competitive sports unless carefully supervised by a competent physician. Permanent physical injury has resulted in the past which might have been prevented by careful watching; and the same harm will occur in the future. In most of the schools we visited an earnest effort has already been made to watch the boys more carefully; but, in our judgment, it was more in the direction of copying the college athletic training, in the effort to turn out winners, than with the idea of individualization and careful medical supervision. Even a competent supervisor is hardly capable of discriminating in some of the border-line cases cited above as to whether to permit exercise, to increase or to diminish it. The school physician examines each boy in the fall and again whenever called on to do so; but we found no definite, purposeful method of physical or urinary examination before or after such a functional test as we applied; nor any plan for an examination by the school physician before and after hard-matched games, although the frequency of the latter in some of the schools was quite as striking as at colleges. One of these physicians told us that some of the boys grew so rapidly that the fall examination was of little or no value in the spring.

It is not the province of this paper to discuss the significance of albumin and casts in the urinary analysis

before and after exercise. Darling and others have shown that albumin and casts appear very often in the urine of young healthy adults after severe exercise. But some of our specimens showed albumin and casts before exercise and others showed a considerable amount of albumin and a great many casts after exercise. Such cases are evidently on the border-line between health and disease, if not beyond it, and merit careful supervision and individualization. Nor do we propose to dilate on the type of physical examination or functional test. A mile run is obviously too severe a strain for some boys, but, if so, these boys should not be allowed to compete in hard contests. From the results of the tests we made it is evident that many of the boys require as much careful supervision over their athletics as they do over their lessons.

It is an important question to determine the advisability of so much devotion to athletics among school boys; but it is within the range of this paper only to urge proper medical supervision over a part of the schoolboy's life, which in his eyes at least is quite as important as his studies. Colleges foster the spirit of competitive games; newspapers dilate on them; the age demands athletic development in the youth; but a growing boy, crowded hard at his lessons so as to pass his college examinations, may not be able to withstand repeated and continued athletic training.

48 West Fifty-first Street.

ABSTRACT OF DISCUSSION

Dr. De Lancey Rochester, Buffalo, N. Y.: I was much interested in Dr. Potter's paper, because of the occurrence of three cases of serious heart trouble which developed in boys under my observation who were engaged in school athletics. A point not brought out in the paper was the evil occasionally resulting from jumping. I have seen one case of flatfoot from this. I think one of the most serious things in athletic contests is the fact that they are contests. Games in schools are very good for the children; but I think that competition, which enters so largely into these contests, makes the boys overdo it to a great extent. Moreover, athletics are now appearing in the lower grades of schools, and I have now under observation two boys, 8 years of age, who have been injured by these athletic contests in school. These children are encouraged by their masters, and I believe there is great danger of the masters encouraging the boys too much, urging them on in these athletic contests to the physical injury of the boys.

Dr. Richard C. Cabot, Boston: Dr. Potter's paper backs up the conclusions reached by Dr. Darling of Cambridge in his observations on certain athletes, such as football players, An interesting point which Dr. Darling emphasized is that in fatigue we get conditions, not exactly healthy or exactly diseased, according to ordinary conceptions. He found in fatigue states not only a marked leucocytosis, but abnormal forms of leucocytes, such as are not to be discovered at all in health. Yet all these things apparently work no permanent harm to the individual. In one of Dr. Darling's cases (after a boat race) anyone would have said that the urine showed an acute nephritis; there was present a large amount of albumin, blood and many casts. Yet within a few days the urine was normal again. To me an interesting point is that from mere fatigue such changes can be produced in the heart, the blood and the kidneys. I should like to ask Dr. Potter the reason for this "reversed blood pressure." Why was it greater in the horizontal than in the upright position?

Dr. Stanley P. Black, Pasadena, Cal.: I should like to know how many of these athletes develop endocarditis, a severe endocarditis. I am afraid that we are developing heart troubles in the children. A child of 8 years is now taught to run one mile. I have seen young children run until they fall from exhaustion, unconscious on the track. I think it is an outrage that such is allowed, and the medical profession should enter a protest against the manner athletics is often carried on.

Dr. Nathaniel Bowditch Potter, New York: We attempted to estimate the blood pressure in the horizontal and in the upright position, because Dr. Meylan, in examining students at Columbia University, found that students whose vertical pressure was lower than the horizontal pressure needed careful watching. In our observations we hoped to find something definite from the test, but I can not say that we did. Many of the boys showed rather excessive fatigue after the race, presented a greater amount of albumin and a larger number of casts, or showed an abnormal heart's action, and some of these boys exhibited a reverse pressure which most of the others did not. In one of the schools where I examined six boys before and after a quarter-mile run, one boy exhibited a marked cardiac enlargement and a reverse blood pressure. Six years before, while at home on his vacation, Dr. Favill of Chicago asked Dr. Billings to examine the boy's heart. The boy had a dilated heart.

THE USES AND LIMITATIONS OF EXAMINATIONS OF THE STOMACH CONTENTS *

CHARLES G. STOCKTON, M.D.
BUFFALO, N. Y.

The stomach-tube should not be too small; for an adult it should be from 30 to 35 French scale. It should not be too flexible; it should support its own weight held in the upright position for the length of twelve inches without bending. It should have the largest-caliber possible without making it liable to bend sharply at an angle when pressed on. A good deal depends on the quality of the rubber; much depends on the character of the tube. It should have no pumping apparatus connected with it and it should be about 54 inches long.

On the introduction of the tube it is occasionally grasped by the esophagus about 8 or 10 inches from the teeth. If this delay is temporary, it depends on spasm, and one may expect to find either cardiospasmus or stricture at the cardia.

Finding portions of the test meal returned when the tube has passed about 14 inches, the food being unmixed with gastric juice, is evidence of obstruction of some kind at the cardia, the retention of food in the esophagus and probably dilatation of the latter.

If in pressing the tube onward it stops at the cardia or, engaging in a spasmodic contraction, is held fast, we may infer the existence of stricture or spasm at the end of the esophagus.

On passing the tube into the stomach we usually obtain the best reflow at a distance of from 21 to 22 inches from the teeth, provided the patient is an adult of ordinary stature, having the stomach in position and of normal size.

Where the stomach is high this result may be obtained at 18 inches. In a very tall person the tube may have to be passed 24 inches or beyond, even when the stomach is in a normal position.

When the tube is passed 20 to 22 inches we may find stomach contents; and on aspirating this, the tube being pressed further on, after a little resistance, it apparently gets into a second cavity from which stomach contents of different character is removed. This indicates an hour-glass stomach or a spasmodic contraction of the stomach between the second and the last third of the organ; in other words, at the antrum pylori.

When, after passing the tube the usual distance, we find present an unusually large amount of the test meal at the proper time, it indicates moderate motor insufficiency of the stomach which may depend on atony or on some opposition at the pylorus.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

If we find a large quantity of the test meal present undergoing fermentation, having a "musty" odor, showing a large quantity of bacteria and sarcinæ and full secretion of hydrochloric acid, with few lactic acid bacilli, it is indicative of benign obstruction at the pylorus.

If we find stagnating food of foul odor, either with or without free hydrochloric acid, with lactic acid present, together with the Oppler-Boas bacilli and unchanged or occult blood, it suggests malignancy and obstruction.

The presence of too little of the test meal at the usual time with, however, the presence of gastric juice, suggests overmotor activity.

When we find the stomach empty or find present too little of the test meal and no gastric juice, it indicates excessive motor activity, probably associated with achylia gastrica (frequently present in pernicious anemia).

A conclusion should not be reached by a single examination. On one day there may be found the absence of gastric secretion and on the next an excess of it. On one day the food may be retained beyond the usual time and on another it may have passed onward too quickly. From this we conclude that the patient is the subject of nervous disturbance, perhaps excited by the very practice of lavage.

When we find habitually an acidity above 60, depending on hydrochloric acid, free or combined, the presence of hyperchlorhydria is suggested.

Hyperchlorhydria, however, is not to be determined by a given standard. The secretions of the stomach are seldom stable and should not be fixed by positive laws. A secretion normal with one person is excessive with another. In other words, some patients suffer from the symptoms of hyperchlorhydria when the secretion is decidedly below the standard. Such patients may be victims of gastric hyperesthesia.

There are cases of practical suspension of the gastric secretory function with symptoms similar to those of hyperchlorhydria; these are probably instances of chronic glandular gastritis with exacerbations accompanied by symptoms of irritation.

Overacidity, with delay in digestion of starch, is indicative of hyperchlorhydria.

A high total acidity, depending mostly on free hydrochloric acid, suggests a defect in secretion of enzymes.

A high total acidity, depending largely on combined chlorids, suggests an active secretion of the enzymes.

The presence of mucus in excess should always attract attention. Large quantities of glairy, ropy mucus, unmixed with the test meal, indicates esophageal mucus which has entered the stomach through the irritation occasioned by the passing of the tube. It often occurs when the tube has been introduced in a clumsy manner. It is not indicative of gastritis.

Finding a mass of nummular sputa, often accompanied by pus and by epithelium from the respiratory tract, indicates that the mucus has been swallowed and is not of stomach origin.

When mucus is found thoroughly intermixed with the test meal, usually not glairy or ropy, it probably comes from the gastric mucosa, and is indicative of catarrhal gastritis.

The presence of occult blood, or blood cells having undergone change by digestion, is evidence that hemorrhage has taken place in the stomach with active secretion such as occurs in ulcer.

If the blood cells are found intact it speaks for recent hemorrhage or lack of digestive power, or both.

The presence of blood with mucus and pus cells, apparently not coming from the respiratory passages, with fragments of tissue, suggests ulceration or degeneration of the gastric mucosa and probably malignancy.

A slow return of the gastric contents through the tube, showing little pressure from below, is indicative of atony and probably of dilatation.

Finding food remaining after washing for a considerable time is evidence of atony and probably dilatation.

Finding that the stomach holds, without inconvenience, a large quantity of fluid is indicative of dilatation; however, testing the capacity of the organ in this manner is a practice not recommended.

On the other hand, if the stomach contents return through the tube with some force, it indicates a strong motor activity or a stomach greatly overdistended with contents—certainly a high pressure. (Under such circumstances we should attempt to rule out the elements of strong contraction of the abdominal muscles.)

A forcible return may occur in dilatation provided there is hypertrophy of the muscle walls as a result of pyloric stenosis.

Violent or spasmodic spurts, coming from the stomach-tube, result from sudden contraction of the abdominal muscles and a suddenly increased intra-abdominal pressure.

When bile is found in the stomach contents it probably depends on relaxation of the pylorus with upward pressure of the duodenal contents through contraction of the abdominal muscles, or reverse peristalsis.

When the proximal end of the tube is held beneath water and bubbles of gas escape through it, it is indicative of an excess of gas in the stomach.

When no gas escapes from the stomach, even though the patient complains of continuous eructations, it may be argued that the gas is not formed in the stomach by fermentation, but that we are dealing with a hysterical condition.

The slow change of albumin, especially of meat fibers, shows that the gastric digestion is retarded.

The presence of the odor of fatty acids, of a "musty" or vinous odor, is evidence of fermentation.

Too much importance should not be attributed in stomach examinations to the disturbances in secretion.

The greatest importance should be attributed to evidence of disturbances in motion.

The diagnosis of stomach diseases should not be made solely by examination of the gastric contents, but by the results of this method considered in connection with the symptomatology and with the estimation of all the facts in the case.

Wrong conceptions will arise from basing a diagnosis on stomach examinations alone, or on too infrequent examinations; or on examinations conducted without rules and without thought.

The stomach-tube is of the greatest importance in the matter of diagnosis; in treatment it is often useless and sometimes pernicious. Nevertheless it is at times a therapeutic agent of great efficiency and cannot be replaced by any other measure in poisoning cases, gastrectasis, before operation in obstruction, in some cases of intractable vomiting, in catarrhal gastritis and, in general, for the relief of an irritable gastric mucosa.

It should be much more generally employed than it is as a routine in general examinations, but, as in other physical methods of examination, the results will depend on the expertness and thoughtfulness of the examiner.

436 Franklin Street.

X-RAY EVIDENCE IN GASTRIC CANCER*

A. W. CRANE, M.D.
KALAMAZOO, MICH.

The treatment of cancer of the stomach rests in the hands of the surgeon, but the diagnosis rests in the brain of the physician. He is the first to see the case. If he fails to make an early diagnosis the surgeon can give no hope. And yet early diagnosis is often impossible even with the advantages of experience and the laboratory. For these reasons I hope to interest the internists of this Section in a comparatively new factor in the early diagnosis of cancer of the stomach. This factor is the *x*-ray plate.

The use of the *x*-ray in diseases of the alimentary tube depends on the fact that the inside of the stomach or intestine, when coated with a salt of bismuth, casts its shadow on plate or screen. In such shadows lie the *x*-ray evidence of gastric disease. These skiagraphs are not self-interpreting. A known and constant technic is a condition precedent. In addition to an *x*-ray training we must bring to bear the physical examination of the case, the laboratory findings, the inspection through the incision at operation, and the investigations of the post-mortem. The larger the record of a collective experience of many workers the more exact and comprehensive will be the interpretation of skiagraphs.

This illustrates the fact that we are in the primitive stage of the *x*-ray diagnosis of gastric cancer, and justifies me in assembling the diagnostic factors deducible from the *x*-ray image of the inner wall of the stomach, so as to consider those attributable to cancer.

The diagnostic factors presented are:

1. Size.
2. Form.
3. Position.
4. Clearance.
5. Location of pain-marker.

The size of the stomach must be judged by the size of the patient. The form of the stomach, which is subject to change without notice, may nevertheless clearly be designated as:

1. Normal stomach.
2. Tubular stomach.
3. Globular stomach.
4. Drain-trap stomach.
5. Deformed stomach.
    a. Indentation stomach.
        (1) From spleen or other adjacent organ.
        (2) From tumor in stomach wall.
        (3) From tumor outside stomach.
    b. Adherent stomach.
    c. Contractured stomach.
        (1) Forming pucker in body of stomach.
        (2) Forming hour-glass contraction.
        (3) Forming partial or complete stenosis at pylorus.

The position of the stomach may be normal, or may be displaced as a whole, or may suffer a displacement of certain parts, namely, the fundus, the greater curvature and the pylorus with its antrum.

If the center of pain, or of tenderness on pressure, be marked by a lead letter (P) fastened to the skin by adhesive plaster, we may find the demonstration of this displacement of the stomach or its parts, with reference to the lead letter as depicted on the *x*-ray plate, to be a matter of decisive importance. The stomach or its parts may extend to unexpected places. The lead marker, which we thought lay over the appendix, we may find to coincide with the pylorus; or, again, the lead marker, which we thought lay over the stomach, may lie over the pancreatic area, the stomach having prolapsed out of the way. Incidental to a stomach examination we may demonstrate the lead marker of pain or tenderness to coincide with the duodenum or some other portion of the small intestines, some part of the colon, or the spleen, liver, gall bladder, kidney, ureter or urinary bladder. But the position of the lead marker must not be implicitly relied on to localize the lesion. For example, a circumscribed abdominal pain may be due to a Pott's disease of the spine high up in the dorsal vertebræ, beyond the field of the stomach plate.

Our fourth factor, the clearance of the stomach or its power to empty its contents, depends on:

1. Position of greater curvature.
2. Position of pylorus.
3. Pyloric stenosis.
4. Pyloric insufficiency.
5. Hour-glass constriction.

An analysis of these diagnostic factors presented by stomach skiagraph shows that three out of five major factors may give information concerning gastric cancer. They are:

1. Form.
2. Location of lead marker.
3. Stomach clearance.

In the case of cancer the alterations of form are those of the indentation or contractured type of the deformed stomach. In the case of ulcer the alteration is confined to the contractured type. The indentation stomach is therefore the type distinctive of cancer. A benign growth would have to be excluded on other grounds.

The factor of stomach clearance is observed in the last plate. If bismuth remains an unusual time in the stomach, there may be a pyloric narrowing or an hour-glass contraction due to the scars of old sores or to indentations. Lastly, if the lead marker lies over a certain portion of the stomach and the case history shows the location of pain or tenderness to be constant, then we may add this fact to the other clinical data favoring cancer. By the same reasoning, if the marker lies over the duodenum we may suspect duodenal ulcer.

But the *x*-ray diagnostician must never judge a case from *x*-ray signs alone. He must possess himself of the entire clinical and laboratory records. The *x*-ray amplifies but does not supersede other means of diagnosis, although it often happens that the skiagraph supplies the missing premise of a diagnostic syllogism.

The problem of differential diagnosis may require a careful consideration of all available evidence in the case. When we find a deformed gastric outline we have to discriminate between an indentation from the pressure of other organs or growths; a local contraction of the stomach wall; an invasion of the stomach wall by a growth; and the presence of adhesions due to disease of contiguous organs. Also when we find low clearance and a globular form, and establish the fact of pyloric narrowing, we then have to discriminate between narrowing due to the scar tissue of ulcer; that due to growths in the walls of the antrum or pylorus; that due to pressure of growths or glands outside of the pylorus; and that due to binding of adhesions.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In order to make these discriminations we must study the stomach under normal conditions so as to be able to recognize a departure from normal outlines. The normal stomach is more vertical than horizontal and lies above the plane of the umbilicus. Laterally, the axis of the stomach is oblique to that of the trunk, the fundus lying to the back and the pylorus to the front, so that when the patient is placed horizontally on his back the stomach contents gravitate to the fundus and, when placed on his abdomen, to the pylorus. The fundus is in contact with the diaphragm above, the left lobe of the liver to the right, and the spleen to the left and back. The main body of the stomach lies posteriorly in contact with the tail of the pancreas, the left kidney and suprarenal. On the left side it lies in contact with the spleen, the splenic flexure of the colon, the transverse colon, and the descending colon. On the right it lies against the vertebral column and the abdominal vessels. The antrum pylori at the back lies against the pancreas, while the whole stomach in front lies against the abdominal wall. The displaced or dilated stomach may lie in contact with any and every organ in the abdominal cavity.

When we consider the contact relations of the stomach we see that a study of the indentations of the stomach walls may in different cases yield information concerning almost every abdominal organ.

Our technic must be adapted to these anatomical conditions. Air or bismuth within the stomach gives certain outlines. In actual practice by the bismuth method we have to do with the combination, since air or gas is always present to some extent. We must consider the following points:

Patient.
1. Position of body.
2. Degree of stomach distention
3. Contents of stomach.
4. Immobility.

Bismuth.
1. Kind of salt.
2. Quality.
3. How suspended.
4. How taken.
5. How distributed.

Time of day for exposure of plates.
1. Relation to meals.
2. Time elapsing between ingestion of bismuth and exposure of plate.
3. Number of plates and time between.

The patient may be in any position, but the best skiagraphs will be obtained by placing the patient horizontally, front down, on the plate.

Only by the horizontal position can we prevent the bismuth by its weight from deforming the true gastric outline. The preservation of the true gastric outline also depends on the degree of stomach distention and the nature of the stomach contents. The stomach should be empty to begin with and the distribution of bismuth should be such as to reveal most surely any indentations, contractures, or adhesions. This part of the technic must be an approximation because we can only approximate the size of the stomach preceding our x-ray plate.

Immobility of the patient may be obtained by having the breath held. Practical immobility of the stomach may be obtained by sufficiently rapid exposure, or by morphin. Morphin, however, destroys to a large extent the value of the second and third plates by interfering with the factor of stomach clearance and the intestinal distribution of the bismuth.

Nearly all of my stomach work since 1905, until two months ago, has been done with bismuth subnitrate. With the exposure of the final plate I have always given a full dose of Epsom salts. An average of three cases in a hundred, however, have shown some slight toxic symptoms consisting of faintness, cyanosis, slight pains and stiffness of the legs from ten to twenty-four hours after. With the Epsom salts following, I believe that bismuth subnitrate may be safely used. The subcarbonate, however, first suggested to me by Dr. Pfahler, gives equally good skiagraphs, and is free from the possibility of the decomposition of the nitrate radicle with the formation of poisonous nitrites.

The method of mixing the bismuth with some kind of foodstuff so as to fill the stomach does not meet our diagnostic requirements. The aim is not to fill the stomach, but to coat its walls; not to show a large bolus of food and bismuth, but to define stomach outlines. To this end the bismuth should be introduced into the stomach in the thinnest menstruum that can be swallowed. This is plain water.

The quantity of bismuth needed is, according to the size of the patient, from 40 to 100 gms. in from 250 to 500 c.c. of water. This is immediately distributed over the rough and furrowed mucosa of the stomach by placing the patient in the horizontal position, back down, on a swivel surgical chair or table, which is then tipped into the Trendelenburg position, head lowered, feet up. We may then slowly rotate the chair while the bismuth is settling upon the stomach lining, where it will be retained for a time which is more than ample for skiagraphic purposes. The patient is then directed to turn over via the left side, face down, without rising out of the horizontal, after which the chair is again tipped, head down, and rotated as before. From three to five minutes are sufficient for these maneuvers. The patient, now in the horizontal position, face down, arches the abdomen to allow a plate to be placed beneath. He then lies on the plate, care being taken to bring the arms forward so that the weight of the body is not supported by the elbows. A 14 by 17 plate should be placed so that the forward edge is on a line with the nipples. The tube should then be fixed, not closer than 50 cm. (or about 20 inches), over the center of the plate. The radial axis is then always in the center of the plate and need not be marked by plumb, as in my earlier plates.

If the preparations have been complete, including the previous fixing of a lead U in the umbilicus and a lead P over the center of the area of pain or tenderness, if such exist, then we shall be ready to turn on the x-ray in from five to fifteen minutes after giving the bismuth. The patient is directed to take a moderate breath and hold it as long as he can without moving in any way. This allows us from five to thirty seconds, according to the size of the patient, and ensures a serviceable negative in every case. The shorter the time the clearer-cut the negative. But all the time up to thirty seconds may be allowed which the apparatus requires.

The first plate (14 by 17) may be conveniently exposed in the morning after the test breakfast has been withdrawn for analysis. Then, an hour after the first plate, a second plate (10 by 12 or 8 by 10) should be exposed under a compression diaphragm so as to take in any area which the first plate shows as abnormal. If no such abnormality appears, then one should focus over the critical area within which lie the antrum pylori, the pylorus, the duodenum, the head of the pancreas and the common duct. Six hours after the first plate, or the time between two meals, a third plate (14 by 17) should be exposed. This will demonstrate stomach clearance, confirm gastric deformities, and show the intestinal distribution of the bismuth. If the first plate is exposed before dinner the third may be exposed before supper. After the first plate the meals should be eaten as usual.

As to the technic of coil, tube and plate, I would say only that skiagraphy of the alimentary tract by the bismuth method is hard-tissue skiagraphy, the bismuth areas often greatly exceeding the bones in density, as shown by stomach negatives.

The progress of the bismuth is often astonishingly rapid. In five minutes after the bismuth is taken a portion of the duodenum will commonly be coated. In fifteen minutes bismuth may be found in the jejunum, and not infrequently in coils of the ileum. In four hours the stomach may have emptied itself; and in four to six hours, the small intestines, by their vigorous peristalsis, may have passed the bismuth clearly and completely into the colon, where it may be distributed from the cecum to the sigmoid.

These points and each essential condition and factor mentioned in this paper are illustrated by seventy-two plates placed in observation frames in the Scientific Exhibit. Lack of time prevents me from demonstrating them on this platform. These are the best of several hundred plates taken by myself in the course of a private and consultation practice, and have been carefully labeled and described by typewritten sheets posted on the frames. I have been aided in the interpretation of each plate by my relation of physician to the patient, by a necessary familiarity with the clinical and laboratory findings, and by attendance on most of the cases for subsequent periods. When operation or autopsy has followed, such is indicated on the plate. This exhibit is arranged particularly for medical men who are not *x*-ray experts, because so many medical men, even some of national fame, seem strangely unaware of the possibilities of the *x*-ray plate.

I believe that sufficient stomach work has already been done by numerous *x*-ray operators in various parts of the world to demonstrate the incomparable value of the *x*-ray in cancer of the stomach as well as in a wide range of other affections of the alimentary tube. Medical men should study *x*-ray plates of their cases. It is no exaggeration to say that the *x*-ray plate and screen will give often more and better information than an exploratory operation. This is emphatically true in the case of gastric ulcer, but holds true in the main for gastric carcinoma. Where the diagnosis of malignant disease is not in doubt the *x*-ray should still be used, because few medical or surgical diagnoses are so exact and comprehensive that the skiagraph and screen may not extend or revise our knowledge.

In conclusion, I take pleasure in acknowledging my indebtedness to Dr. C. M. Spencer, my clinical assistant, for his very able service in this work.

Teaching of Dermatology.—T. Caspar Gilchrist, in his presidential address before the American Dermatological Association, states that the teaching of dermatology of to-day and for the future means much harder work than formerly, as the dermatologist must not only convey his knowledge to the student by personal practical teaching, but must also advance the knowledge of our branch of medicine by investigation and experimental work, otherwise his horizon must inevitably grow narrower.—*Journal of Cutaneous Diseases.*

THE DETERMINATION OF TRYPSIN IN THE STOMACH CONTENTS AFTER OIL TEST MEALS *

CLIFFORD B. FARR, M.D.
PHILADELPHIA

The experiments reported in the following paper are based on the work of Boldireff and Volhard. The former in experiments on dogs found that the introduction of oil into the stomach caused regurgitation of duodenal contents, in which the presence of pancreatic ferments could be demonstrated; the latter devised a new method for demonstrating the presence of trypsin and applied Boldireff's discovery to clinical uses.

A. OBJECTS, METHOD AND RESULTS IN GIVING OIL TEST MEALS

My first object was to substantiate the observations of others as to the ease and frequency with which duodenal contents might be obtained after the oil meal.

The second was to decide which of the methods proposed was best suited for detecting trypsin in the specimens secured.

The third was to discover what, if any, clinical value was to be attached to the findings thus obtained.

The oil meal as given, consisted of 100 to 200 c.c. of olive-oil or cottonseed-oil; in most cases this was given through a tube; occasionally the patients preferred to drink the oil. While the tube was in the stomach, before the oil was administered, any contents present were aspirated or washed out. In the case of a large dog, in which repeated attempts to obtain duodenal contents had failed, lavage with sodium bicarbonate solution, as well as the administration of magnesia, was tried without effect. In one-half to one hour, the oil was aspirated. In many cases a few cubic centimeters of whitish mucoid fluid, in addition to a small amount of oil, was all that could be recovered. In other cases a large amount of pale green or dark curdy green fluid, amounting in one case to as much as 250 c.c., was obtained. With this was a supernatant layer of unchanged oil and an intervening zone of soap-like emulsion. The tests were carried out in the separated white or green fluid without previous filtration.

The following is a summary of the oil test meals:

18 oil test meals were obtained from patients.
5 oil test meals were obtained from a large dog.
1 specimen was aspirated from the duodenum of a dog by intubation.
Twenty-four specimens in all were examined.
6 of these were of a light or dark green color.
18 were transparent, milky or in a very few cases brownish.
3 of the green specimens showed the presence of trypsin.
3 of the green specimens showed the absence of trypsin.
4 of the colorless specimens showed the presence of trypsin.
14 of the colorless specimens showed the absence of trypsin.

In addition four Ewald test meals, mostly green in color, were examined; one showed the presence of trypsin.

In practically all cases more or less fluid was obtained; frequently this was nothing more than a small amount of retained or possibly newly secreted gastric juice and mucus. It seemed to me, therefore, that the only criterion as to the character of the juice should be its color, indicating or not indicating the presence of bile, and its response to tests for ferments. A third factor might be the amount obtained. Judged by this standard, only nine out of the above eighteen tests on human beings can be considered successful. This differs widely from the results of a recent writer who was successful in 48 out of 50 cases. This disparity may be accounted for partly by my lack of experience, but more largely, as I shall point out, by his faulty controls. My conclusion, therefore, is that Boldireff's plan is superior to those previously suggested, but is by no means uniformly successful as several writers have intimated.

B. COMPARATIVE VALUE OF METTE, VOLHARD AND GROSS METHODS OF TESTING FOR TRYPSIN

Of the numerous methods proposed at various times for the estimation of pepsin and trypsin only two or three, which have been used for the purpose under consideration, will be considered. Most of the others are too complicated for clinical use, or else offer no advantages over those here discussed. The Mette method, as I have described it in several previous articles, was employed and needs no minute description, as it is now fully given in the text-books. In using it for trypsin the contents were usually diluted with decinormal sodium carbonate solution, thus affording the most favorable conditions for tryptic digestion. Particles of fibrin were placed in each dish to detect traces of digestion.

The detailed technic of the Volhard method may be omitted, but it is necessary to give an outline to explain the principle on which it is based. A strong casein solution of a definite strength and alkalinity is prepared. To a measured portion of this alkaline fluid a definite amount of neutralized duodenal juice is added, and digestion allowed to proceed at 37 C. for twenty-four hours or other fixed period; then a definite but excessive amount of normal hydrochloric acid is added and the precipitation of the casein brought about by sodium sulphate. The amount of precipitate is found to be in inverse ratio to the amount of ferment, and on filtration the acidity of the filtrate, as tested by titration with decinormal sodium hydrate solution, is found to be increased directly in proportion to the amount of ferment. A control is used in each case, the acidity of the control being subtracted from that of the specimen under examination. The exact directions for the preparation of the solution are appended.

The method of Gross, which is very similar to the one simultaneously devised by Fuld, also utilizes casein as the substratum for digestion. A solution of casein, 0.1 per cent., in 0.1 per cent. sodium carbonate solution is prepared and 10 c.c. decanted into each of several test-tubes. The trypsin solution serially diluted is added and the tubes incubated for twenty-four hours. At the end of that time 1 per cent. acetic acid solution is added to each of the tubes and the dilution noted in which cloudiness is still produced. If the casein is completely digested no cloud appears.

The tests were employed first with artificial trypsin or pancreatin solutions and, secondly, with the contents obtained by Boldireff's method. Previous work with the Mette method had convinced me that it was a good, though not delicate, qualitative test of artificial trypsin solutions. In testing duodenal contents, however, I was unable to obtain any positive results. Particles of fibrin were frequently added to the dishes and almost invariably showed digestion in cases in which Volhard was positive. By the Volhard method eighteen specimens obtained from patients or from dogs after the oil meals, as well as several specimens of feces and ordinary stomach contents, were tested. Numerous experiments were also made with artificial solutions. In almost all cases the minutest traces of trypsin were clearly indicated. In a number of instances in testing duodenal contents a marked disparity was noted between a water control as used by Volhard and others, and a control consisting of the boiled specimen to be tested. These differences, as shown in the accompanying tables, were sufficient to counter-balance the low figures obtained in many of the positive results reported by others. I was also unable to obtain any definite quantitative results; occasionally the titration showed acidities closely corresponding in relative amount to the comparative strength of the trypsin solutions employed, but in the majority of instances in which trypsin solutions of varying strength were simultaneously tested, the stronger solutions gave higher results, but the figures bore no definite relation to the concentration of the ferment. In some cases this correspondence in results may have been due to the fact that the weaker solution gave a maximum effect. My conclusion was that the Volhard test had little value as a quantitative method, but was a delicate and reliable qualitative method.

The Gross test seemed to be a delicate one, but, as its inventor states, it is not suited without modification for use in duodenal contents, as bile salts and other constituents give rise to a similar precipitate which is liable to cause confusion.

TABLE 1.—OIL TEST MEALS FROM PATIENTS*

---

* This table shows a few typical cases. Nos. 1 and 2 may be regarded as negative, No. 3 shows a small amount of trypsin. Nos. 4 and 5 larger amounts. Water is shown not to be a sufficient control.

† The page numbers refer to laboratory note-book.

My inclination in the future would be to use the Mette method and a simplified Volhard test in a purely qualitative way to control each other. I would use mensuration in the former and titration in the latter only when the results were doubtful.

The accompanying examples (Tables 1, 2 and 3) from my note-book have been arranged in tabular form to illustrate (1) the details of the dilutions and calculations, as well as (2) the results obtained by different methods and by the use of natural and artificial trypsin solutions.

Let us now pass to the clinical side of the question. My cases are too few in number to be of much value, so that after a brief outline of my results, I shall review the valuable or suggestive findings of others. As stated above, I have excluded from consideration all cases in which neither bile nor trypsin was present. This unfortunately limits the usefulness of the test, but seems to be unavoidable.

In four cases some affection of the pancreas was present or suspected.

Case 1.—In the first patient, the diagnosis of cancer of the pancreas was made at operation. Previous to operation 50 c.c. of green fluid had been obtained *after an oil test meal.* Volhard's test gave an increase in acidity of 9.4. Unfortunately water only was used as a control. *Trypsin was probably diminished in amount or possibly absent.*

Case 2.—The second case was one of cancer of the prostate with secondary growths. After an oil test meal, 3 c.c. of white fluid were obtained. The fibrin test for trypsin was positive; the Mette test was negative. At autopsy a secondary growth was found in the pancreas with necrosis of the tail of that organ and subdiaphragmatic abscess.

Case 3.—The third case presented indefinite intestinal symptoms which were said to have been relieved by pancreatin. The case was considered to be a gastrointestinal neurosis. Two oil test meals were examined, one specimen was white and gave a *low positive result* by Volhard (7.0); the other was green and contained no trypsin. The latter result seemed to be the more trustworthy.

Case 4.—The fourth case was referred to Dr. Edsall as a probable case of pancreatic disease, but he could not confirm this opinion. His diagnosis was intestinal indigestion. After an oil test meal 45 c.c. of greenish fluid was aspirated which proved to be free from trypsin by Volhard's test. In these four cases the method seemed not only to give no assistance in the diagnosis, but even to be more or less inconsistent with the clinical findings.

Cases 5 and 6.—In two cases of cancer of the stomach, strongly positive results were obtained by the Volhard test; in the first 32.8, in the second 29.7. In neither case was there any pyloric obstruction since in one the orifices were not involved, while in the other a partial gastrectomy had been performed. It has been suggested that there is a vicarious digestion in the stomach by means of trypsin in cases of impaired digestion. Strange to say, however, there was no reduction of the gastric activity in either of these cases.

The three remaining cases show nothing of interest and may be given in Table 4.

TABLE 4.—Oil Test Meal and Volhard's Test in Three Cases

Case.	Diag.	Quantity.	Color.	Volhard reading.
7	Chronic gastritis, with anacidity.	Small amt.	White.	4.0 (control water).
8	Hyperacid gastritis.	60 c.c.	Clear green.	0.0
9	Gastric ulcer.	250 c.c.	Green.	16.8

Oil juice was found active by Volhard in 9 out of 11, by Faubel in 23 out of 37, by Lewinski in 19 out of 27, by Molnár in 48 out of 50 cases. Boldireff, in a dog, was able to demonstrate the presence of trypsin before tying, and its absence after tying the pancreatic duct. Hemmeter and Lewinski found trypsin absent in the duodenal contents in cases of obstruction of the bile duct due to stone. Volhard, in a case of pancreatic diabetes, was able to verify the diagnosis of atrophy of the pancreas. He also found trypsin in two cases and was thus able to exclude pancreatic disease, which had been suspected. In 22 cases of achylia he missed trypsin only once. He found the same to be true of subacidity, and believes that this offers a plausible explanation of the good peptonization observed in these cases.

CONCLUSIONS

1. The duodenal contents may frequently be obtained after the oil test meal, though sometimes there is doubt as to the character of the fluid aspirated.

2. On this account it may be possible to exclude atrophy of the pancreas, but only under very unusual conditions can we demonstrate its presence. In a number of diseases the examination has yielded suggestive results.

3. The observation of Boldireff is of more interest from the point of view of pathologic physiology than of diagnosis, for example, in gastric ulcer and in achylia.

4. The casein method of Volhard is a delicate qualitative test for trypsin, but for this purpose needs simplification.

5. The regurgitation of the alkaline intestinal juice induced by oil may explain the therapeutic value of the latter in some cases of hyperacidity.

Finally, I desire to express my thanks to Dr. Robert G. Torrey for aid in performing the tests.

REVIEW OF LITERATURE

Boas: Centralbl. f. klin. Med., 1889, No. 6, x, 97; Ztschr. f. klin Med., 1890, xvii, 155.
Tschlenoff: Cor.-Bl. f. schwerz. Aerzte, 1889, No. 6, xix, 161.

Boas described the first systematic method for obtaining the duodenal contents. His plan was to massage the abdomen in the region of the gall-bladder and left lobe of the liver and afterward to aspirate any fluid that might have been forced into the stomach. In about fifty cases he obtained active intestinal juice in which he was able to demonstrate amylolytic, lipolytic and proteolytic ferments. He states that the tryptic action of the pancreatic secretion in weak acid or alkaline solutions is the only decisive test. He gives a complete description of the duodenal contents, which holds good for the fluid obtained by the oil method.

---

* Many similar tests were made which agreed substantially with those given above.

Tschlenoff was able to obtain intestinal juice in five out of seven patients by the Boas method.

Hemmeter: Arch. f. Verdauungskr., ii, 85.
Kuhn: München. med. Wchnschr., 1896, No. 29, p. 674.

Hemmeter asserted that he was the first to introduce a methodical procedure for obtaining the duodenal contents by intubation of the duodenum. Kuhn's instrument is much simpler and better than Hemmeter's but either one requires too much technical skill to admit of its general use in clinical diagnosis.

Einhorn: New York Med. Jour., 1908, No. 25, lxxxvii, 1179.

Einhorn has modified his "bucket" for the purpose of obtaining the contents of the duodenum for examination.

Goldschmidt: Deutsch. med. Wchnschr., 1909, No. 12, xxxv, 522.
Gross: Ibid, 1909, No. 16, xxxv, 706.

Goldschmidt and Gross, using the latter's method for detecting trypsin, have recently discovered this ferment in the feces of all normal persons examined. This does not agree with the observations of previous writers, but if confirmed will render the use of oil test meals quite superfluous.

Boldireff: Zentralbl. f. Physiol., 1904, No. 15, xviii, 457; Centralbl. f. Physiol. u. Path. d. Stoffwechs., 1908; No. 6, viii; Arch. f. d. ges. Physiol., 1907, Part 1, cxxi, 13.

The following is a condensation of Boldireff's most important conclusions. After fatty food, in cases of excessive acidity, and after long-continued fasting, a mixture of the pancreatic, intestinal and hepatic secretions pours into the stomach. This fact is utilized to obtain pancreatic juice and bile for examination, and must also be taken into account in tests to determine the acidity, the ferments and the motility of the stomach. Boldireff believes that when fatty food is taken gastric digestion is carried on largely by the ferments of the pancreas. He also states that none of the hypotheses which have been proposed to explain the fact that the stomach does not digest itself take the reflux of pancreatic juice into account. He thus hints at a new theory for the explanation of gastric ulcer. Hyperacidity does not increase the peptic power of pepsin but does favor regurgitation of pancreatic ferments.

Volhard: München. med. Wchnschr., 1907, No. 9, liv, 403.
Faubel: Beitr. z. chem. Physiol. u. Path. (Hoffmeister), 1907, x, 35.
Löhlein: Beitr. z. chem. Physiol. u. Path. (Hoffmeister), 1906, vii, 120.
Molnár: Ztschr. f. klin. Med., 1909, Parts 1-3, lxvii, 188.

Volhard was the first to employ Boldireff's plan for clinical purposes. For testing the "oil juice" he modified his pepsin method. The casein solution required is prepared as follows:

One hundred gm. of finely granular casein are added to 1 liter of distilled water treated with 80 c.c. of normal sodium hydroxid and made up to 2,000 c.c. with chloroform water. The mixture is slowly warmed on the water bath, with frequent shaking, till all the casein is dissolved, and then quickly raised to 85 or 90 C. to destroy bacteria and ferments. After cooling, a layer of toluol is added to prevent access of bacteria.

An individual test is carried out as follows:

One hundred c.c. of casein solution are placed in a flask marked at 300 and 400 c.c.; chloroform water is added to the mark 300 and then an accurately measured amount of trypsin solution (5 or 10 c.c.) previously neutralized. (The acidity may, however, be noted in advance and the necessary corrections made after the final titration.)

Control flasks are prepared in a similar manner, distilled water taking the place of trypsin solution. After incubation for a definite period of time, 11 c.c. of normal hydrochloric acid is added to each flask and then complete precipitation brought about by filling the flasks to the 400 c.c. mark with 20 per cent. sodium sulphate solution. After complete filtration 200 c.c. of the filtrate from each flask is titrated with decinormal sodium hydroxid solution, using phenolphthalein as an indicator. The acidity of the control is subtracted from that of the ferment containing solutions. In my tests the only modification of this method was in the use of a different preparation of casein from that recommended by Volhard (not obtainable in this country) and in the use of half the quantities recommended by him (Merck's Casein [Hammarsten] was used). My results were multiplied by two so as to compare with the results of other writers. Volhard and his followers found that trypsin as tested by this method did not follow the Schütz-Borrisow law.

Gross: Arch. f. exper. Path. u. Pharmakol., 1907, Parts 1-2, lviii, 157.
Lewinski: Deutsch. med. Wchnschr., 1908, No. 37, xxxiv.

Lewinski used the oil method in 27 cases, using the Gross test to detect the presence of trypsin. At first he was unable to obtain trypsin in hyperacidity cases, but afterward by giving half a teaspoonful of magnesia before the oil and again in twenty minutes, he was uniformly successful. He thinks that failure to obtain active juice shows pancreatic insufficiency or mechanical interference with the passage of the pancreatic secretion into the stomach.

211 South Seventeenth Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. STOCKTON, CRANE AND FARR

Dr. G. E. Pfahler, Philadelphia: We know so little that is definite in the diagnosis of cancer of the stomach that everything in advance in this line must be welcomed by all. If the members of the section will examine the plates which Dr. Crane has so carefully prepared, and which may be seen in the scientific exhibit, they will be convinced that the *x*-ray is not an illusion, but gives evidences of cancer. I have seen 35 cases of carcinoma of the stomach; some came to autopsy, while in the others the patients came to operation. In the majority there was no palpable tumor present. In the cases in which there was a palpable tumor it had to be differentiated from tumors of some other part of the intestinal tract. Very valuable evidence is given in this line by the *x*-ray. I think that the sooner the medical man gets in mind the actual and true position of the normal stomach, and forgets what has been considered as classical, the sooner will we enter lines of progress. It is hard to convince a man who is not familiar with the *x*-ray of its value in these cases. As a matter of fact, only one-half the evidence is obtained by the *x*-ray plate; the other half is obtained on the flouroscopic screen. Movements, such as the peristaltic movements, are not revealed on the plates, and I think these form the basis of a positive diagnosis, an early diagnosis. A little induration in the stomach walls, especially if occupying the lesser or greater curvature, causes a change in the wave, but this evidence cannot be obtained on the plate. Of course, a study of the plate by an experienced man is important.

I believe that unless we apply the pain-marker over the seat of pain and move the stomach, to determine that the point of pain moves with the stomach, it is of not much value. I think evidence found at autopsy will bear me out in this.

One must examine these patients in at least two positions, both the vertical and the recumbent. If in the vertical position with proper manipulation, moving the patient sideways, working on either side of the spinal column, will bring out all the evidence that is possible. I have been using bismuth subcarbonate and find it entirely satisfactory. In an examination of 365 patients for conditions affecting the gastrointestinal tract, in whom I used from 2 to 3 ounces of bismuth subcarbonate, I found no toxic symptoms, or a single symptom that could be traced to the use of the bismuth. I think this is a perfectly safe method. The only objections I can see are that too much time and patience are required and, also, one is put to a considerable expense. But these objections can be overcome.

Dr. A. W. Crane, Kalamazoo, Mich: One caution occurred to me in drawing conclusions from stomach contents obtained at different levels by the stomach tube. This is illustrated by one *x*-ray plate in the scientific exhibit on Young's Pier taken with the stomach tube in place in the stomach. It may there be seen that the cardiac orifice is on the side and not on top of the stomach. This orifice passes into the stomach toward the upper part of the great curvature. In many cases the end of the tube stops there, as shown by the skiagraph. If a further introduction of the tube is attempted the tube bends; the point does not descend. This is true in a certain proportion of the cases. In this particular plate it is determined beyond a doubt. In many cases in which the stomach contains but little, the contents can be obtained by placing the patient on his back in nearly a horizontal position; then the stomach contents flow upward to the fundus and can be easily drawn off with the tube. Again, in the so-called hour-glass stomachs, when there is a constriction between the upper and lower sacs, the opening is generally too small to permit the passage of the tube. In these cases the stomach contents are obtained from the upper sac, and would not differ in any respect from the contents of an esophageal diverticulum. I doubt if any man can tell whether the end of the tube is in the upper sac of an hour-glass stomach in which the constriction is high up, or in a diverticulum. The attempted diagnosis of such conditions with a stomach tube is open to serious objections. The *x*-ray plate is necessary.

Dr. Judson Daland, Philadelphia: During the past three years I have seen a number of cases of gastric tumors studied by *x*-ray, and it seems to me from the experience gained that so far as gastric carcinoma is concerned the entire work is in its very beginning. At the same time, we must acknowledge that the *x*-ray does aid us materially and in many directions. Often it makes clear the position of the tumor, whether gastric or not. It seems to me that it is especially important to be able to determine the peristaltic waves, if they can be plainly and distinctly seen. I believe that the fluoroscope has a value of more than one-half that of the skiagram. By the use of the screen one obtains, on the whole, more information than can be obtained by the skiagram. However, both methods must be employed. The use of bismuth in *x*-ray work is a welcome addition to diagnosis, and all the work that is to be done should be done with as much enthusiasm as has been shown in the past. By paying more attention to the work more definite signs than we now possess will be brought out. We need much more *x*-ray evidence than we now possess, and we must acknowledge that we have little evidence of carcinoma of the stomach, particularly in the early stages, when a diagnosis is most important. The use of the subnitrate of bismuth in doses of from 2 to 3 ounces for *x*-ray work I have seen give trouble which was of no particular importance; there would probably be a gastrointestinal irritation for two or three days and then it would pass away. Its occurrence was rather unusual and therefore did not constitute a bar to the further use of the *x*-ray. I think the subcarbonate is to be preferred to the subnitrate of bismuth.

Dr. Allen A. Jones, Buffalo: It is misleading when one attempts to judge the position and size of the stomach by means of the stomach tube; one cannot say that he is dealing with a normal stomach, a stomach in a normal position and of normal size, when the tube is used for this purpose. The contents may come through the stomach tube anywhere from nineteen inches or lower, even to twenty-six inches in normal cases. The contents may be obtained from the fundus or from the pyloric extremity. I was interested in Dr. Crane's statement in regard to hour-glass contraction of the stomach; he found it was impossible to differentiate between the contents obtained from the fundus and that obtained from a diverticulum of the esophagus, from a dilated esophagus, or from a stenosis from any cause. This emphasizes the extreme importance of the pyloric region of the stomach. Unless there is a proper mixture of gastric juice with the food at the pyloric extremity of the stomach, the stomach content does not assume normal characters. One point that Dr. Stockton mentioned was of considerable interest; this was the condition of the emptying function of the stomach with achylia gastrica. Recently considerable interest and significance has been attached to the chemistry in the duodenum and the pyloric closing and opening. It has been taught that, in normal digestion, when the duodenal contents reach an acid point, that is, a certain degree of acidity, a reflex action occurs which results in the closure of the pylorus, and no more contents are allowed to pass on until that which is already present is neutralized and has probably passed down further in the duodenum. If that is true, theoretically the passage of the gastric contents must be much hurried in achylia gastrica. But clinically such is not the case. We frequently find the contents retained in the stomach as long as would obtain in normal digestion. These are the cases in which we are apt to have symptoms of achylia gastrica. Peristalsis is, after all, the most effective measure, or means, of emptying the stomach contents into the duodenum, provided there is no pyloric stenosis and regardless of the fact that there is a low gastric acidity. On the contrary, however, it is in achylia gastrica that many marked cases of pyloric insufficiency and hurried emptying are observed.

Dr. John A. Lichty, Pittsburg: At the risk of being considered a psychiatrist, I wish to call attention to the effect of the mind or nervous system on these patients in whom we think it necessary to use a stomach tube. I believe that in the first days that the stomach tube is used the findings are of very little value, especially if the patient is a nervous one. If you tell the patient that you will pass the stomach tube on him next day he will worry all night about it, wondering how the stomach tube is going to feel. It certainly does have some effect on the digestive secretions, so much so in fact that the findings are of little value. I have also proved this in dogs. In our experiments on dogs we found that the dogs became fond of their keepers and the keepers could pass the stomach tube without any difficulty whatever; in these cases the stomach contents were found to be constant and normal. But one day one of the students asked me to let him go down and assist the janitor. All the dogs then had either diarrhea or vomited. This influence of the nervous system is not more so in dogs than it is in human beings. I wish to emphasize a point that Dr. Jones has mentioned in regard to the use of the *x*-ray, that is, the *x*-ray findings. Unless the stomach tube is passed up toward the pylorus the secretion withdrawn is not going to give a definite idea of the gastric secretion; one cannot always be sure of it. However, if the patient takes the tube nicely and easily, the physician then can rest assured that normal gastric secretion has been obtained. In spite of all this, I doubt whether the findings are always correct and that we can always make a correct interpretation of the findings. In those cases in which we have a definite clinical history we should disregard the gastric findings if they do not agree with the history. One should study the clinical history as much or more than the gastric findings.

Dr. Henry R. Harrower, Chicago: I believe that there is a possibility of mistake regarding the finding of the Oppler-Boas bacillus which the text-books lead us to believe is pathognomonic of gastric carcinoma. I have been misled in my brief experience by finding them in a number of gastric analyses; they were undoubtedly Oppler-Boas bacilli, but no malignancy was associated with them at all. At least two years have passed in one case, and this patient is not suffering from any gastric disturbance whatever. I have in mind a man who was suffering from some serious stomach disorder which was diagnosed as cancer. He vomited practically everything that passed into the stomach and was dying of starvation. I made a careful examination of the gastric contents and found a large number of what I believe to be Oppler-Boas bacilli. I think these bacilli can be easily recognized after one has seen them a few times. This patient was treated with ordinary digestants and eventually gained seventy pounds; in a year he was perfectly well. The Oppler-Boas bacillus is not pathognomonic of gastric carcinoma and this should be emphasized more, and the statements made in some text-books should be changed.

Dr. John N. Upshur, Richmond, Va.: I do not think that there is a more interesting subject than the study of stomach troubles. I am satisfied that the best men are sometimes in error as a result of their conclusions the result of analysis of gastric contents. If they could find it possible to be at both ends of the tube at the same time, that is, be the patient as well as doctor. I was one of those unfortunate people who had serious stomach trouble. I consulted several stomach specialists, who studied my case carefully. But I found from my own experience that my trouble was a neurasthenic one; it was a dilatation of the stomach of five inches, the result of a deficient motility as the result of a nervous breakdown. Four years later a specialist, who was thoroughly competent, told me that I had no dilatation at all. Now an exceedingly interesting thing to me was the use of the stomach tube. I am sure that I passed the stomach tube on myself at least 2,000 times. For seven years it was impossible for me to have a quiet night and be fit to work on the following day unless I used one gallon of sterilized water before retiring. The interesting feature in my case was that the digestive disturbance always came at the end of the day, when I was tired, mentally and physically. I am satisfied that the benefit, a decided benefit, arose from the use of the tube by causing a stimulation of the stomach with the sterilized water as a massage. The water was used at a temperature that was comfortable. There was an improvement in the motility of the stomach caused by the stimulation of the lavage together with long continued use of strychnin. I have not used the stomach tube for eighteen months and I am now in better physical condition than I have been in ten years and can do as much work as a young man can. What I wish to emphasize is that the best men are apt to make mistakes unless they can put themselves at both ends of the tube at the same time, at one end as the doctor, at the other as the patient; then they can arrive at some definite conclusion.

Dr. C. Urban Smith, Baltimore: I agree with the statement that the presence of the Boas-Oppler bacillus is not positive of carcinoma of the stomach. From what has been expressed here to-day one would infer that its presence was of positive diagnostic value, but we frequently find the bacillus in benign conditions. There is no doubt but that the Gram-positive finding of the bacillus in the feces is a valuable link in establishing a positive chain of evidence. In regard to the withdrawing of the stomach contents, and the statement that all the contents are rarely obtained by the ordinary methods, I wish to say that I find the expression method which is used largely in Germany is probably the best and simplest method to completely empty the stomach when properly performed, but requires a certain amount of practice and experience.

Dr. Frank Smithies, Ann Arbor, Mich.: Dr. Stockton should be praised for the complete résumé that he has given us. It seems to me that a fact not strongly emphasized should be mentioned. In the examination of stomachs the tube is frequently passed without sufficient attention being given to the state of the patient's mouth and teeth. Before the tube is passed it is well to have thorough cleansing of the teeth, mouth and throat. I recently had an experience which strongly impressed this on me. A specimen supposed to be Oppler-Boas bacillus was sent to me. It turned out to be leptothrix from a dirty mouth. I think that greater stress should be laid on frequent examinations of the gastric secretions and contents. Outside of institutions it is common to have a diagnosis offered a patient, based on but one stomach examination. As Dr. Lichty has pointed out, this amounts to but little unless the findings are positive ones, as, for example, the contents showing atypical cells, bacilli, etc., at this examination. With respect to the x-ray evidences in the diagnosis of cancer of the stomach, I must frankly admit that "I am from Missouri." From a somewhat careful examination of the plates submitted, I must say that I see little that would lead one to differentiate between early cancer or ulcer. And it must be remembered that it is in the early cases that we are justified in recommending refinements of diagnosis. A study of the abdomen with the aid of a fluoroscope frequently tells us important things respecting gastric and intestinal motility. But I fail to see that the x-ray offers any more information or more exact information than one can gain from careful examination with the aid of the stomach tube at appropriate sittings. And it should be emphasized that the stomach tube is always at hand.

Dr. Alexander Lambert, New York: Has Dr. Crane noticed in the skiagraphs of cancer of the stomach any relation between the pain described by the patient and the tenderness as elicited by the examination? As we know, the abdominal viscera refers pain to the abdominal wall. Has he drawn any conclusions; is there any relationship between the place of pain, as described by the patients, and the seat of the lesion as elicited by x-ray examination in cases of gastric carcinoma?

Dr. Philip King Brown, San Francisco: It is not an easy matter to differentiate the Boas-Oppler bacilli, and it cannot be done positively by simple staining methods. There are two definite types of organisms closely resembling the Boas-Oppler bacilli, and found commonly in stomach contents and stool. One is not uniformly positive with the Gram stain and has the same morphology as the colon group; Schmidt calls it the pseudocolon type. The other is very difficult to differentiate from the Boas-Oppler bacillus in stained specimens, except that it is slightly larger and thicker, and appears in long chains in the stool. It is also Gram-positive. What Dr. Smith has said is true; but be certain you are getting the Oppler-Boas bacillus before telling the patient that he has cancer.

Dr. Charles G. Stockton, Buffalo: Hour-glass stomachs are not seen frequently; it is not a common condition. A stomach tube could not pass through such a constriction readily, although I have done it in two cases. I feel convinced that the statements I have made will stand, with some exceptions of course. What Dr. Jones has stated in regard to the distance of the tube is perfectly true. Dr. Lichty's statement regarding the mental impression on the gastric secretions is correct and I am glad that he emphasized it as he did. The conclusions drawn regarding the stomach condition from one or two examinations are often misleading and throw the practice into disrepute. As to the Oppler-Boas bacilli, I think what has been said is true, but it has been said more strongly than I would say it. These bacilli are found in conditions not cancerous, but not in such abundance or regularity that I imagine one would believe from hearing what has been said. They are not at all pathognomonic of cancer. But when they are found in abundance they certainly have a diagnostic bearing, especially when taken in connection with other findings. Their presence does not stand alone and by itself in the diagnosis of cancer; this has never been claimed for them.

Dr. A. W. Crane, Kalamazoo, Mich.: If I gave the impression that the x-ray was an infallible means of diagnosticating cancer of the stomach, it was a mistake; it is simply one added factor to the other methods we have. To make plates is comparatively easy, but to interpret them requires understanding and training. To recapitulate briefly, the x-ray evidence of cancer of the stomach lies in the deformity of the normal outlines of the stomach. Ulcers or the scars of ulcers give contractures, while cancer gives an indentation of the stomach-wall. These distinctions are illustrated by many plates in the scientific exhibit. I should like to ask that the medical men give more attention to what the x-ray men in this country have to show them. They will find something in this method of diagnosis applied to the stomach.

The Changes in the Glandular Epithelium of the Uterine Mucosa in the Intermenstrual and Premenstrual Periods.—Material for the investigation was obtained from fifty-seven normal women whose menses were regular and abundant. The specimens were fixed in Zenker, Flemming and alcohol, and stained with safranin, hematoxylin and eosin, van Gieson and mucicarmin. From his histologic observations, R. Schröder (Inaug. Diss., University of Rostock, 1909), draws the following conclusions: The glandular epithelium of the uterine mucous membrane exhibits, eleven days after the beginning of menstruation, peculiar substances in the protoplasm of the cell, which have no affinity for staining reagents. These first make their appearance in the form of very small globules, which then grow larger and ultimately break through the cell wall and escape into the lumen of the gland. Along with these changes another substance makes its appearance in the glandular epithelium. It is characterized by its marked affinity for hematoxylin, and is first seen at the periphery of the cell. Soon the entire cell is filled and the stainable substance is next found in the lumen. It is thought that the glandular epithelium of the uterus is at all times, or at practically all times, capable of secreting mucus. The above changes, in all probability, represent different stages in the secretion of the peculiar uterine mucus.

THORACIC SURGERY *

P. L. FRIEDRICH, M.D.
MARBURG, GERMANY

While fully appreciating the distinction conferred on me by your call to read a paper before this meeting on the present state of thoracic surgery, I realize that the prescribed time limit demands a concise handling of this subject. My assistant, Dr. Sauerbruch, was enabled to tell you last year at Chicago of his own ingenious studies and experiences, so that I can briefly dismiss the details of the method of operating under positive and negative pressure.

The surgery of the lung and the heart, as well as of the mediastinum, the diaphragm and the esophagus, are entitled to the greatest interest and attention, the outcome being governed by the manner of surgical interference. All these fields accordingly become criteria of eminent rank for the quality of our technic.

Surgical intervention on the affections of the lung may be classified under four different headings:

I. Intrapulmonary interference with diseased foci.

II. Influencing of pulmonary affections by way of the pleura, through compression of the lung.

III. Operative procedures on the thoracic wall, for the mechanical influencing of the pulmonary function, thereby reacting on pathologic processes in the lung.

IV. Operative treatment of the diseases of the thoracic wall itself, in as far as this leads to the exposure of the lung.

I shall say only a few words in regard to the management of pleural empyema later on.

I. INTRAPULMONARY INTERFERENCE WITH DISEASED FOCI

Simple intercostal incision is almost invariably the procedure of election for penetrating into the lung. Under employment of the differential pressure method, it affords complete information concerning the existing condition in the lung, and serves, therefore, as a sort of exploratory incision. With the lung open to inspection, and with control of the pneumothorax, the organ may be very completely palpated in all its parts; moreover, by artificially changing the pulmonary circulation, through variations of the pressure, the differences in color of healthy and diseased tissue may further be accentuated, and in the same way the lung may be put on the stretch or caused to relax. In the pressure-difference chamber operations are readily performed within fluctuations of 3 to 8 mm. mercury without endangering the patient's life or running the risk of pneumothorax. Hence, this procedure at the present day is almost a necessary requisite for exact anatomic planning and judicious conduct of the operation. In the treatment of wounds of the lung, as well as in all aseptic interventions on the organ, for the extirpation of tumors of the lung or of the chest wall, it greatly facilitates the work of the operator.

The dangers of pneumothorax for the circulation and respiration are lessened, it is true, by its gradual development, so that the affected lung segments may be drawn out and operated on, under tamponing of the remaining pleural space. But just as the risk of infection, in subsequent operative interference, is certainly increased by the preliminary application of pneumothorax (Dollinger), through revolutionizing of the lymphatic circulation in the pleura, we likewise add to the danger when we operate in the presence of pneumothorax, or when we close wounds before the pneumothorax has been entirely removed. Infection represents the most serious danger of all endothoracic operations, and whatever serves to prevent its occurrence becomes a part of the indispensable outfit of the operator.

The intercostal incision is sufficient, as a rule, even for extensive foci of disease or injury, whereas the removal of a considerable portion of one or two of the neighboring ribs is almost exclusively reserved for cases of gangrene or abscess. In lung injuries we aim at closing the wound by direct suture (Garré), if possible, perhaps after trimming the margins, where these are ragged or soiled (Fig. 1). The lung is then dropped back into the thoracic cavity, and this is closed with sutures. I recommend either the inverted suture (Fig. 1, a, b, c) or the penetrating suture (Fig. 1, d and e) for suturing the lung, silk serving as suture material. Abscess and gangrene of the lung still require suturing of the diseased segment to the thoracic wall, opening the pathologic focus in the same or in another time. Particularly in the case of injuries, the discovery of small wounds is greatly facilitated by the differential pressure method; the artificial production of circulatory changes affording reliable guides as to the source of the hemorrhage.

With special reference to tumors of the lung, the sum total of our clinical experience is as yet far too small for the outlining of the general technic. We know, however, that large segments of a lobe, or even an entire lobe, may be removed, if necessary, as has been shown by animal experimentation and by clinical experience (Heidenhain, Lenhartz, Krause, Garré). The diseased segment of lung is clamped off and then excised well into healthy tissue, under successive hemostasis with the customary measures, partly by direct ligature, partly by acupuncture. It is astonishing how easily hemostasis in the lung may be obtained. The problem confronting our technic is rather the closure of the bronchi in a given case. Bronchial segments devoid of cartilage may be freed from their mucosa (see instrument, Fig. 2), and then closed by direct ligature and acupuncture. But as soon as the cartilaginous area of the bronchi is reached, our technic is still unreliable, and it is not yet decided how often the opening of these bronchi will necessitate a partially open treatment of the wounded lung area. It is then advisable to reduce as far as possible the size of the pulmonary wound by suture, all but the large bronchial lumen, keeping the bronchus open at first toward the outside, by fixing the lung to the chest wall. At the German Surgical Congress[1] in 1907 I have shown the point in the bronchi where any lung amputation must stop, on account of the impossibility of definite bronchial closure, and the grave danger for the pulmonary plexuses of the vagus nerves. The limit of operability is reached in this region. Lenhartz employed a procedure in two stages: first, firmly constricting the lobe at its base with an elastic ligature, following this ten days later by secondary ablation of the ligated pulmonary segment.

I take advantage of the opportunity to show pictures of my instruments for operating on the lungs (Figs. 3 to 6) as well as a picture of my operating table for this work (Figs. 7 and 8). At the same time I wish to point out especially that all prolonged procedures in the course of operating on the lung must be performed under the

---

* Read in the Section on Surgery of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

[1] Arch. f. klin. Chir., 1907, lxxxii, 1.

most careful covering and bounding of the entire wound area with tampons and compresses. In this respect I agree absolutely with Krause, Helferich and Küttner.

The enormous significance of *x*-ray illumination for the diagnosis of operable diseases of the lung is generally known. With its aid alone, tumors have been recognized in cases in which the most painstaking physical examination failed. Detailed reference to certain corresponding observations in sarcoma and carcinoma would lead me too far and must be reserved for another occasion. Opinions are still at variance as to the relative value of operating in one or two stages in abscess and gangrene. In lung tumors also I leave the advisability of operating in two stages, in many of the cases, an open question for the time being. We are engaged at present in the clinics on work of this character, in which one of your countrymen, Dr. Robinson, of Boston, is taking an active part.

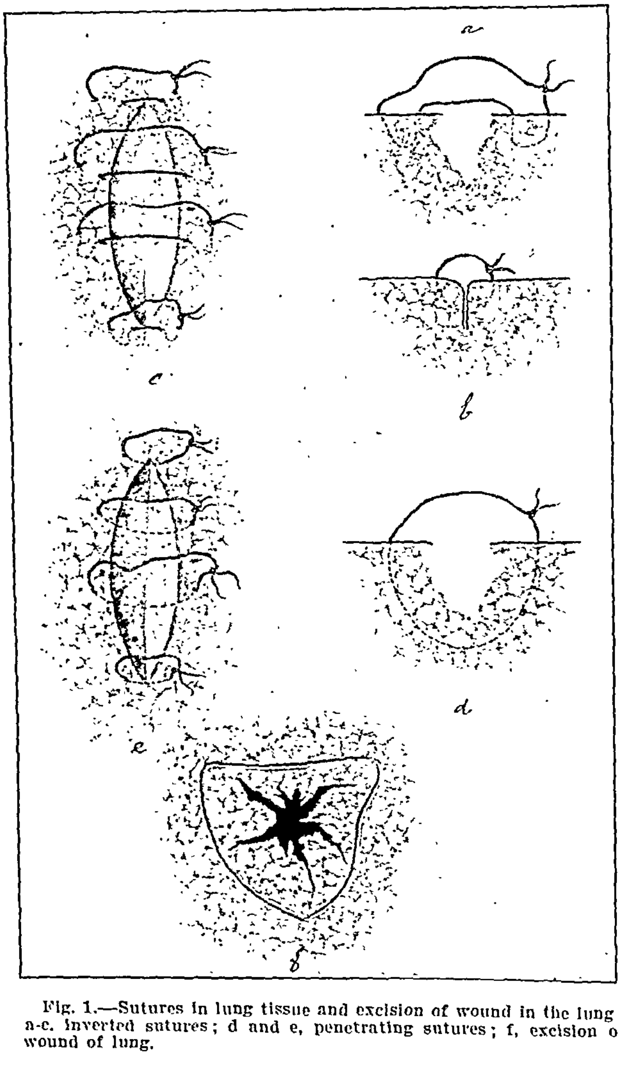

Fig. 1.—Sutures in lung tissue and excision of wound in the lung: a-c, inverted sutures; d and e, penetrating sutures; f, excision of wound of lung.

II. COMPRESSION OF THE LUNG THROUGH THE PLEURA AND THE TREATMENT OF PLEURAL EMPYEMA

The compression of the lung, by way of the pleura, through introduction of air or nitrogen, was recommended in pulmonary tuberculosis by Forlanini, Murphy, Lembke and Schell, Tuffier, Brauer, and in aspirative pneumonia by A. Schmidt. Many among you, I know, are impressed with Murphy's experience. Constricting the volume of the lung, and thereby inducing the shrinkage of the cavernous segments, with the associated influence of the shrinkage on the remaining symptoms, is certainly possible in a series of cases. The scope of usefulness of the method has been much discussed. The technic of nitrogen repletion, after a small pleural incision, is so simple as not to need special discussion. The necessary quickness and the proportionate amount of gas are readily acquired by the operator. The applicability of the procedure is limited, in so far as pleuritic adhesions may represent an insurmountable obstacle. Concerning the actual value and the limits of usefulness of this artificial restriction in volume, it has been found in a large number of cases that the collapse of the lung tissue was followed by subsidence of the sputum and the fever, improvement in the general condition and the physical findings in the lung. The subject has been extensively discussed in the literature of internal medicine.

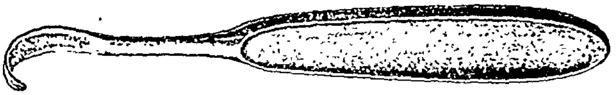

Fig. 3.—Author's double-curved elevator for drawing out the ribs (about two-fifths actual size).

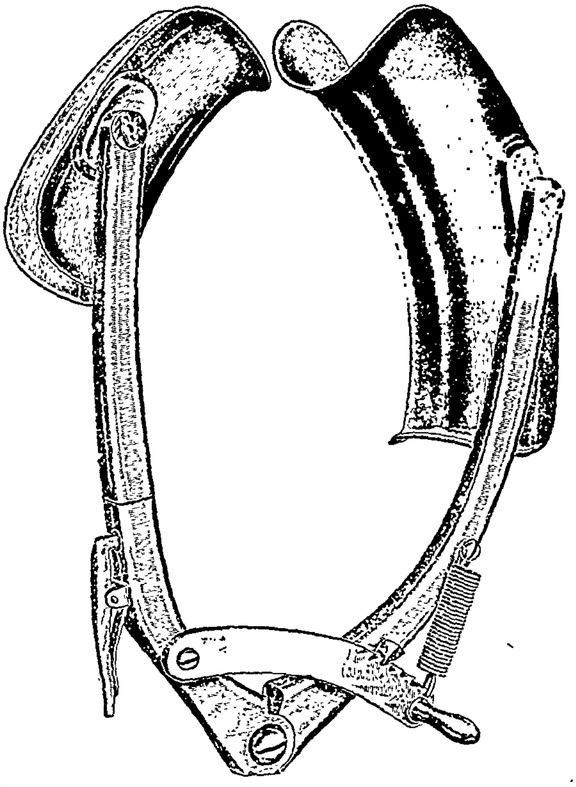

Fig. 4.—Rib-spreader, for use in operations on the lungs; after Mikulicz, modified according to Friedrich (about one-half actual size).

The introduction of the hand, by way of an intercostal incision, in order to enucleate the lung in the presence of adhesions, and to render it compressible, may prove an easy matter, or it may be attended with serious danger, as in one of my cases.[2] In my opinion,

---

[2] Quoted in Surg., Gynec. and Obst., December, 1908, p. 632.

this procedure will prove successful in very exceptional cases only, the more so as but little hope is held out even by direct interference with the knife or the actual cautery, on such diseased segments of lung.

The treatment of pleural empyema, which should be referred to in this connection, will be thoroughly discussed to-day by another speaker, so that I shall limit myself to outlining in a few words our own attitude and technic. Every recent empyema is subjected in the first place to puncture with a thick trocar (or a small thoracocentesis incision), followed by immediate institution of drainage according to Thiersch. This is so imperfectly known that a brief description is desirable. A large fenestrated Nélaton catheter is passed through the sheath of the trocar, a rubber membrane with a small orifice is slipped over it and tied fast to the tube where it emerges, thus providing an air-tight closure of the thoracic cavity at the site of the puncture or incision. If the Nélaton catheter is continued into a soft-walled drainage-tube, which acts after the fashion of a vein, permitting the exudate to escape, under increased internal pleural pressure, while it does not allow the entrance of air, because of the coaptation of its walls in inspiration, the result is a reliable mechanism (Fig. 9) which effectively permits the drainage of the exudate and prevents the occurrence of pneumothorax.

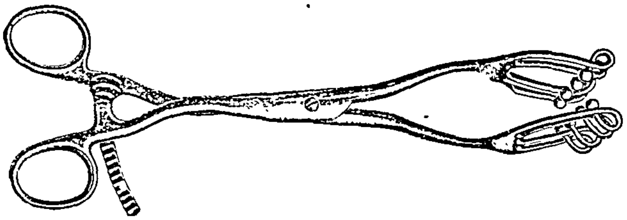

Fig. 5.—Author's lung forceps (about one-third actual size.)

Many empyemas, practically all the metapneumonic cases, are completely healed by means of this apparatus without further surgical assistance. After the pus focus in the pleura has become encapsulated, the resection of one or two ribs may be performed at any time, should the drainage prove insufficient. At any rate this resection has been altogether abandoned by me in recent not circumscribed exudates, because it is here not yet necessarily indicated, requires a longer time, and may be more dangerous through the onset of pneumothorax. Complicated aspiration apparatus is required in rare and exceptional cases only. Thoracoplasty, for long standing empyemas, is sometimes performed only with incisions in the thick pulmonary pleura without decortication of the lung and under partial preservation of the adherent costal picture, as was described by me in the discussion on this subject at the German Surgical Congress of 1898 at Berlin.

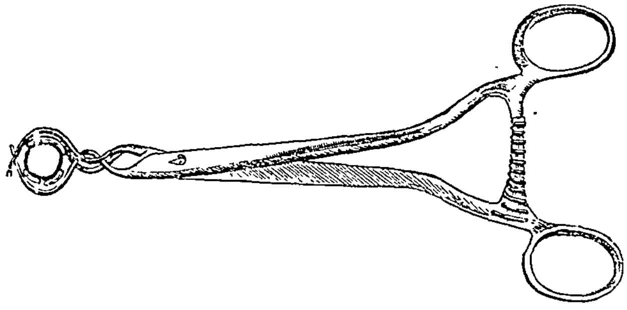

Fig. 6.—Author's hilus-bronchi-clamp, for artificial anemia of the lungs, compression of the pulmonary vessels and leaving open the bronchus (about one-half actual size).

III. OPERATIONS ON THE THORACIC WALL, FOR DISEASE OF THE LUNGS

Among the interventions on the thoracic wall itself, in order to react in this way on the affected lung, operative procedures in emphysema and in tuberculosis have recently acquired prominence. The indications and plan of our thoracoplastic pleuropneumolysis in pulmonary tuberculosis have been extensively discussed by me in several publications, including *Surgery, Gynecology and Obstetrics,* and I have given the details of the proceeding and success of this operation a few days ago at the meeting of the American Surgical Association in Philadelphia.

In the first place I continue to maintain the correctness of my former attitude. The observation of my first cases, now dating back over eighteen months, further confirms the statements made by me at the German Surgical Congress of 1908, to the effect that the majority of the patients operated on are essentially improved, as regards their general condition, increase in body weight, subsidence of cough, sputum and fever. In my last cases, I detached the apex of the lung itself and endeavored to induce its shrinkage. In my most radical procedure of deossification of the chest wall, the first rib had always been preserved, in consideration of the fact that its removal adds considerably to the length of the operation, increases the technical difficulties, and thus heightens the risk run by the patient. In the absence of old periosteal inflammations of the ribs, as a sequel to apicopleuritis, the ablation of the first rib is not, however, attended with special difficulties.

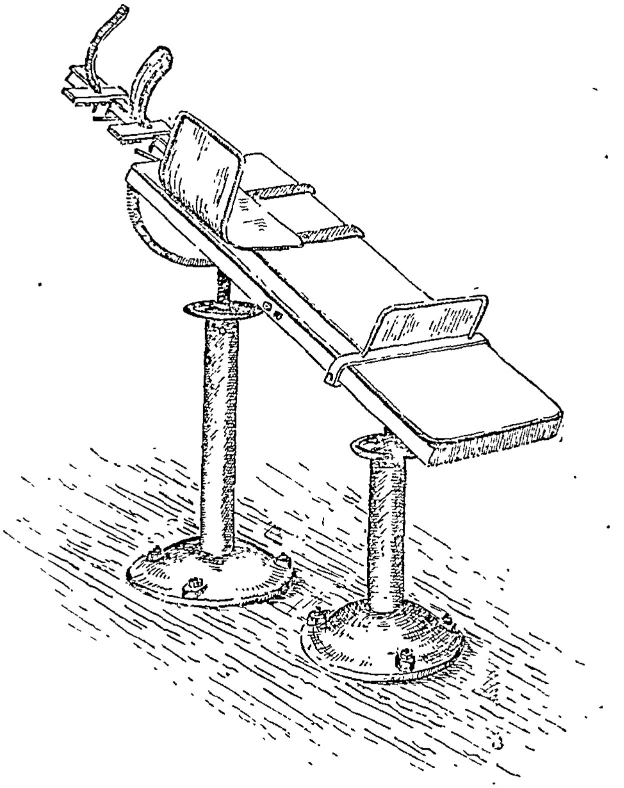

Fig. 7.—Author's lung-operating table.

As has been pointed out in my last publications, the cases should be strictly selected, and only those patients operated on who have unilateral cavernous lesions, with at most passive foci on the opposite side. They must be free from evident recent tuberculous processes in other regions of the body, more particularly the bowel.

Certain recent cases have encouraged me to extend the procedure also to conditions of slowly infiltrating noncavernous phthisis. The arrest of respiration is in itself capable of creating relatively favorable conditions for the cure of this type of phthisis also. In a similar way I have recently endeavored to eliminate an existing tuberculosis of the larynx by means of tracheotomy, and thereby to extend the indications for operating on the lung, but I am as yet unable to express an opinion as to the definite applicability and ultimate outcome under these circumstances. Freund's operation, the division of the first rib for the purpose of counteracting the progress of minute apical lesions, through improved ventilation of the pulmonary apex, I have not ventured on in any instance.

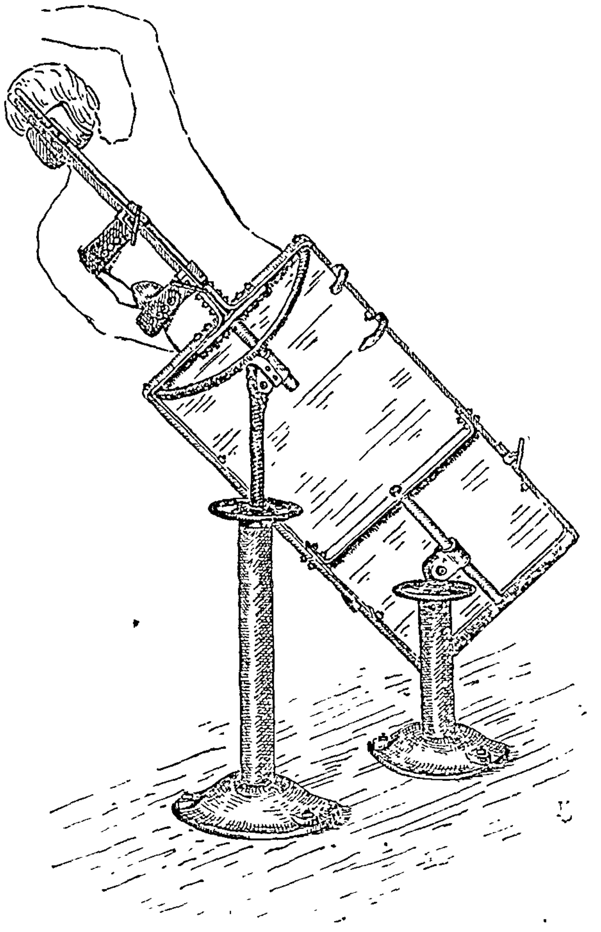

Fig. 8.—Author's lung-operating table, showing position of patient.

Concerning the treatment of pulmonary emphysema, through operative corrections of the rigid thorax by dividing several ribs in their cartilaginous area, I continue to adhere to the modification I have previously referred to, meaning that not only a small segment of cartilage is removed from each rib, as was done by the first operators, in connection with Freund's suggestion, but that pieces of 4.5 to 6 cm. in length are resected at the cartilage-bone boundary of the second to sixth rib, and this procedure followed by careful ablation of the retrocostal periosteum. This procedure has yielded a brilliant operative result in a case of genuine pulmonary emphysema of many years' standing. If the pieces are not long enough, or the removal of the retrocostal periosteum is not sufficiently thorough, a permanent result in the way of improved mobility of the thorax, even purely mechanical in character, can not be guaranteed. I have stated elsewhere that the cases must again be strictly selected for this operation; pure cases of primary alveolar emphysema alone should be operated on, for the time being. In case of all these patients, however, I believe myself fully justified in advocating the operation, which is easy of performance at the hands of an expert surgeon.

IV. OPERATIVE TREATMENT OF DISEASES OF THE THORACIC WALL OF THE HEART AND THE ENTRANCE INTO THE MEDIASTINUM

Tumors of the chest wall may be dealt with at the present day with a certain intrepidity. A number of cases from my clinic have been published, in which a flap of the soft parts was applied directly to the exposed lung, after extensive removal of the chest wall, and healed without reaction. In a case of thoracic sarcoma, in a man 34 years of age, I removed 160 square centimeters of the right diaphragm over the liver, in order to be radical, and the wound healed without interruption. This particular field I am inclined to regard as one in which the differential pressure method will score its first generally conceded triumphs.

The surgery of the heart has likewise been enriched of late by important contributions concerning the indications for operative interference. Especially in injuries of the heart, which in a large percentage of cases are associated with left-sided pneumothorax, I note a very essential advance in the recognition of the cardiac injury, by the rapid control of the pneumothorax through the differential pressure method.

In collaboration in my clinic, Sauerbruch and Häcker showed that the fall of the minimum pressure down to the zero value increases the blood pressure in the body, retards the heart-beat and augments the individual waves. Thus the arbitrary variation of the difference in pressure provides the means for influencing, at will, the sequence of the beats, and the repletion of the heart, in the individual steps of the operation. The pneumothorax will accordingly be maintained during the cardiorrhaphy, and removed for the next following suture of the pleura, in order to have the thoracic cavity filled with inflated lung, and less susceptible to infection. In the experiments, the heart function is invariably retarded as soon as the pericardium is opened, the individual contractions becoming stronger; the heart sometimes bulges out enlarged, the right half being especially voluminous. The hemorrhage is always systolic, becoming diastolic also only in case of large wounds and injuries of the auricles. Bleeding from the left ventricle is as a rule less severe than from the right. I was enabled to demonstrate on the human subject that the employment of the differential pressure method assists in the rendering of the diagnosis and the indications, in so far as the behavior of the pulse did not change with the variation of the pressure differences, the pulse being, therefore, governed exclusively by the heart puncture and the tamponing effect of the blood-filled pericardium on the heart. Furthermore, the hemorrhage from a heart wound is seen to diminish in proportion as the lungs are allowed to collapse. The pneumothorax thus becomes the regulator of the hemorrhage, and is allowed to persist until the suture of the heart has been completed. After the cardiorrhaphy, the pneumothorax is definitely removed, and the pleura and pericardium are sutured. The shaking movements of the heart invariably present during the application of the suture are best controlled by grasping the heart properly, or by means of fixation with a supporting loop.

The intercostal incision alone has been repeatedly advocated of late for the exposure of the heart. At my hands, the ablation of the cartilage of the fifth rib, to an extent of 10 cm., proved very valuable in injury of the right ventricle, after preliminary double ligature of the left mammary artery. One rule will not fit all cases; and the possibility of free inspection should at once be provided, as otherwise much pulling on the heart or bending of the organ may become necessary to render the injury accessible. The ablation of the costal cartilages proved no obstacle for primary wound closing and accurate healing, complete recovery ensuing in a very short time. These experiences with suture of the right ventricle contributed to my adopting a new route for the exposure, especially of the anterior mediastinum; namely, transverse sternothoracotomy. The exposure of the root of the large vessels, as well as entrance into the anterior and posterior mediastinum are enormously facilitated by this mode of incision, with diminution of the dangers, and improved conditions for healing. After bilateral ligature of the mammary artery, the sternum is sawed through from behind with the Gigli saw, and the transverse incision is extended on either side into the intercostal muscle tissue. In this way a sufficiently free access is rapidly obtained (Fig. 10) without sacrificing portions of the sternum or the ribs. In contradistinction, the longitudinal division of the sternum, as practiced in certain isolated cases, not only represents a much more serious and time-consuming intervention, but it has its natural limitations on account of the opposing action of the clavicles and ribs. The removal of a large "Askanazy-glandular tumor" from the anterior mediastinum was successfully accomplished, the case terminating in recovery; also that of a large tumor which grew downward from a pedicle behind the bronchi and the heart, its origin not being properly recognized until the operation. In the second case, both pleura had to be opened at the beginning of the operation, and this proved possible without any disturbance of the heart action during the entire procedure. The patient unfortunately died toward the end of the operation, because of an accidental injury of the wall of the superior vena cava, which was immediately followed by an air-embolism with fatal outcome. These disastrous sequelæ may possibly be avoided in future cases by adopting the suggestion of my assistant, Dr. Schöne, and at once aspirating the air, through a strong pump-syringe (after the manner of Trendelenburg's operation for embolism), from the branches of the pulmonary artery, after temporarily clamping the pulmonary artery or the vena cava close to the heart. Experimentation in my clinic has shown (Sauerbruch and Häcker) that both venæ cavæ may be closed for several minutes, leaving the pulmonary area devoid of a blood supply, without immediately endangering life. On the other hand, personal observation on the human subject has taught me that after complete arrest of the heart action during one to one and one-quarter minutes, the exposed organ will promptly respond again to correct massage, with a rhythmic sequence of beats.

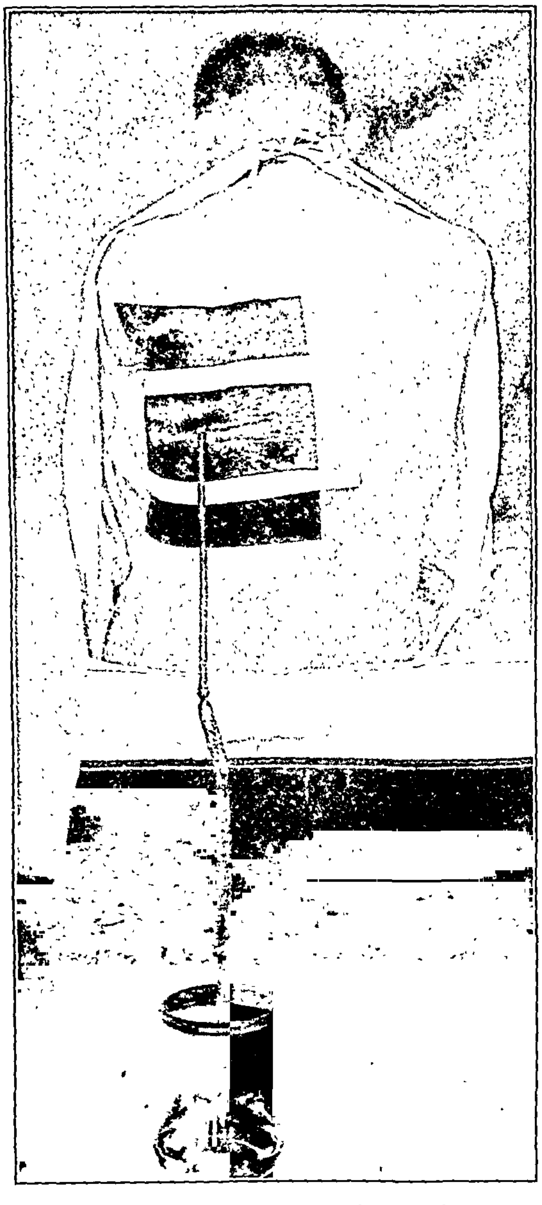

Fig. 9.—Thiersch's drainage.

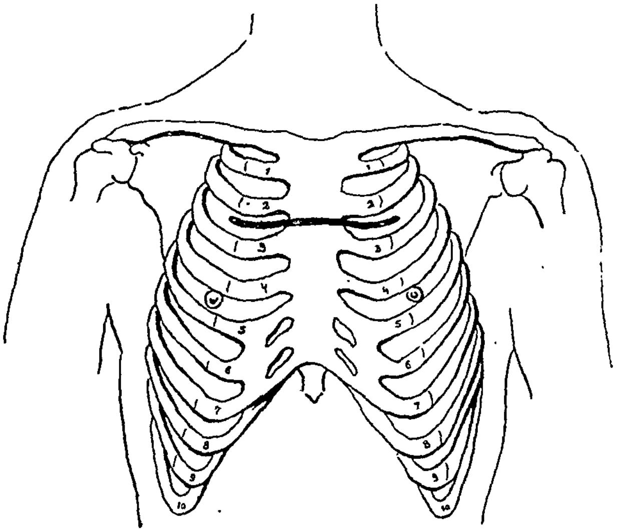

Fig. 10.—Author's transverse sterno-thoracotomy for entrance in the anterior mediastinum.

All the recent experiences of cardiac and mediastinal surgery may be summarized to the effect that by acting promptly, under strict asepsis, after a sharply outlined anatomic plan, we may, with the aid of modern technical devices, anticipate further results which far exceed the limit of what has been accomplished in the past. Successful operative treatment of valvular stenoses of the mitral and aortic valves seems by no means beyond the realm of the attainable.

In conclusion, I wish to add a few words on the resection of the esophagus. Particularly in this connection, the artificial suppression of pneumothorax has induced exaggerated expectations (Mikulicz), but surgical experience is constantly bearing out the views of those who did not consider the prospects in this direction as particularly hopeful. Only the lowermost segment of the esophagus, about 6 or 8 cm. above the cardiac orifice, and the cardiac orifice itself, may still be regarded as legitimate fields for the operation (Sauerbruch, Küttner). Here, again, exploratory thoracotomy can alone afford sufficient information concerning the extent of the disease and the practicability of the operation; and unless the lifting of the stomach through the diaphragm permits the replacement of the lower end of the esophagus we are not justified in speaking of it as a useful operation. The achievement of half-way permanent results, in spite of much earnest endeavor, still remains a desideratum.

I am well aware of the sketchy nature of these remarks, but this mere sketch will serve to show how large a space of time would be required for a fairly complete picture of this special field of surgery.

EXPERIMENTAL INTRATHORACIC ESOPHAGEAL SURGERY *

HENRY H. JANEWAY, M.D., AND NATHAN W. GREEN, M.D.
NEW YORK

During the past year we have limited our work chiefly to intrathoracic esophageal operations. Our aim has been to develop the technic of an operation for each of the following purposes:

1. For circuiting the cardia by the establishment of an anastomosis between the stomach and esophagus.
2. For resection of a portion of both the stomach and esophagus.

We have used two methods of artificial respiration; the one by an inflation of the lungs through an intubation tube; the other by a positive pressure cabinet, similar to that devised by F. T. Murphy and Brauer, in which the head of the dog has been placed.

Each method has had definite advantages. The intubation method has demonstrated two important facts:

1. An artificial apnea is developed which abolishes all muscular effort at respiration during operation.
2. The range of ether-administration is greater and the danger of death from too deep narcosis is less.

The peculiar advantages of the cabinet are the following:

1. The absence of a tube entering the larynx.
2. The smaller quantity of ether required, on account of the pressure of air on the head.

So decided have been the advantages of each method that we have combined the good features of both appliances, and with the cooperation of Prof. Joseph A. Blake, we have had a new apparatus constructed (Fig. 1). It consists of an air-tight box, in the front of which is an opening to receive the patient's head. On both sides of it there are glass port-holes which can be opened and through which the etherizer can constantly view the face of the patient. Below and behind these, at convenient distances, are openings for the etherizer's arms. The posterior one of these is fitted with a rubber valve which prevents the escape of air when the arm is introduced. The front one is closed by the rubber glove suggested by F. T. Murphy, of Boston. This has a long gauntlet and permits the anesthetist to remove the arm at will during the operation. Lights are arranged along the posterior wall for the double purpose of affording illumination and warming the air. The exact shape of the box is unimportant.[1]

The particular feature, however, to which attention is directed is a mechanism situated on the top of the cabinet that permits of a rhythmical escape of air from the box. In virtue of this there is a periodical rise in pressure to the desired height, alternating with a rapid fall to normal atmospheric pressure. The rapidity of this rhythm can be varied at will by the rheostat which controls the speed of the motor and pump. The valve accomplishing this is opened and closed by a commutator turned by a gear and pinion attached to the crank-shaft of the pump. The brush making the contact with the commutator is in series with a helix which operates this valve.[2]

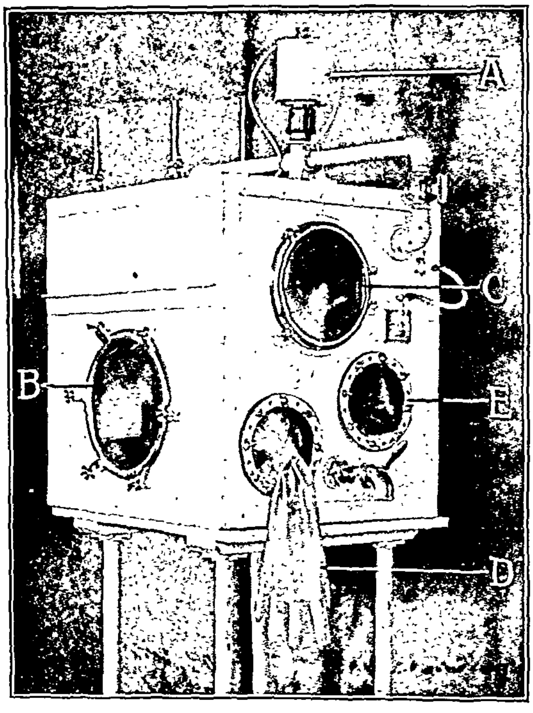

Fig. 1.—Pneumatic positive pressure cabinet. A, automatically working valve for producing rhythmical rise and fall of pressure; B, opening for the head; C, glass port-hole for observing the patient; D, port-hole for the left hand with the glove pulled out; E, opening for the right hand of the anesthetist.

By means of this mechanism practically as complete inflation and deflation of the lungs and the same inhibition of muscular efforts at respiration is obtained as by the intubation method. Professor Blake, for whom this cabinet has been made, has on the human subject demonstrated that such an inhibition occurred. During an

---

* Read in the Section on Surgery of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

[1] We are now having another cabinet constructed which is so arranged that the etherizer is seated behind and introduces his hands through holes in the back wall, and views the patient's head through a port-hole situated in a slanting posterior portion of the roof of the box.

[2] We are now devising a more compact pump and motor which can be placed on the shelf between the legs of the table on which the box rests.

operation for empyema in a child, whenever this device was utilized, the diaphragm and intercostal muscles remained at rest. This contrasted strongly with the respiratory efforts which occurred as soon as the valves were turned which permit of a change to the maintenance of a constant positive pressure. We desire to lay special stress on this point, because the absence of muscular movements during operations in the thoracic cavity contributes in an important degree to the speed and ease of the operation.

TECHNIC OF OPERATIONS

In the past year we have operated on sixty-nine dogs. During the entire time of each operation complete anesthesia by either chloroform or ether was maintained. Our technic has been as follows:

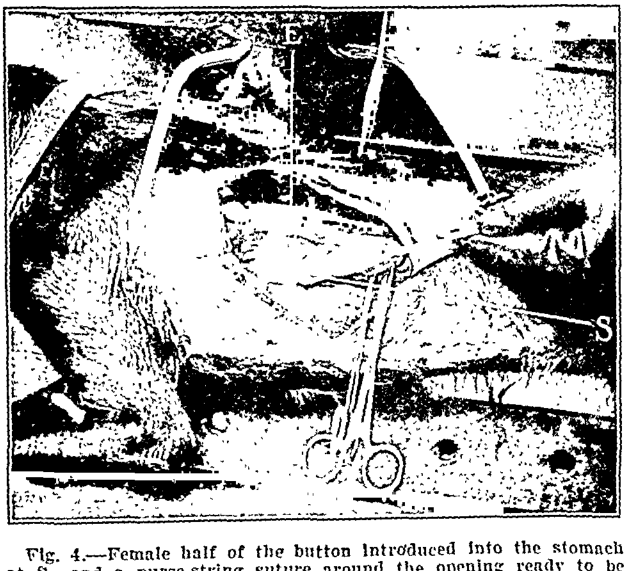

Fig. 4.—Female half of the button introduced into the stomach at S; and a purse-string suture around the opening ready to be drawn up. The male portion of the button lies in the esophagus at E.

1. Gastroesophageal Anastomosis Without Resection. —The eighth rib is first resected subperiosteally. The chest cavity is opened in the periosteal floor of the resected rib (Fig. 2). The peritoneal cavity is opened through the diaphragm, and the anterior wall of the stomach is drawn into the thoracic cavity (Fig. 3). The stomach is opened, the female half of the button is introduced (Fig. 4), and the opening closed by a purse-string suture. The male half, which has been previously passed down the esophagus, is now separated from its carrier and supported for engaging the female half (Fig. 5). This button, which has been designed by us especially for esophageal anastomosis and depends for its union on penetrating needles, is then pressed together. The circle of anastomosis is reinforced by a running suture (Fig. 6). The portion of tissue between the two halves of the button subsequently sloughs out and liberates the button. The opening through the diaphragm is closed by suturing this structure to the wall of the stomach (Fig. 7). Closure of the chest completes the operation.

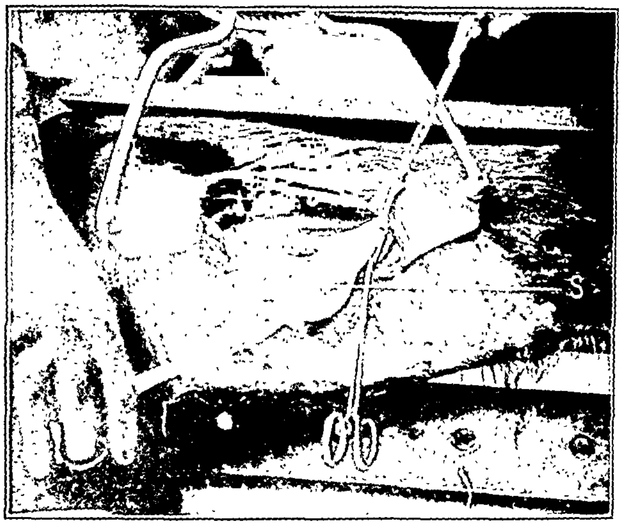

Fig. 3.—Diaphragm opened and the anterior surface of the stomach, S, drawn up through the opening.

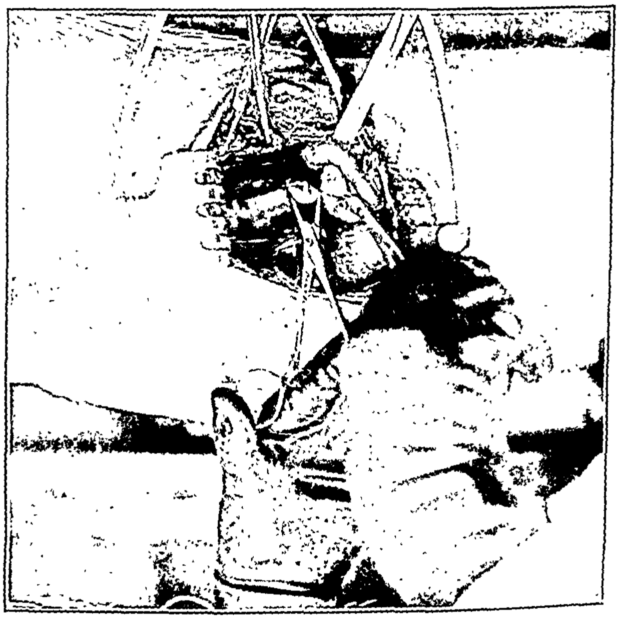

Fig. 5.—The two halves of the button (within the esophagus and the stomach) being approximated and ready to be pressed together.

2. Gastroesophageal Anastomosis with Resection of a Portion of the Esophagus and Stomach.—In this procedure we have found it an advantage to resect both the seventh and eighth ribs, but to open the thoracic cavity in the periosteal floor of the seventh rib. The peritoneal cavity is opened behind (Fig. 8) and in front of the stomach. The gastrosplenic (Fig. 9) and gastrohepatic ligaments are now divided between double ligatures. This permits of the delivery of a large portion of the stomach into the thoracic cavity. The cardia is divided with the cautery-knife between two clamps (Fig. 10). The esophageal stump is protected by clamping over it a gauze pad. Interrupted Lembert sutures are passed from the posterior wall over the clamp to the anterior wall of the stomach. The clamp is now removed, all bleeding stopped, and the female half of the button dropped into the cavity of the stomach. The interrupted sutures are now tied and closure of the stomach completed by continuous Lembert sutures. The esophagus is then amputated by the cautery between a purse-string suture, and a clamp which is applied to the upper end of the segment to be removed. The free end of the esophagus is pushed into the cavity of the male half of the button (Fig. 11), and the two halves are pushed together. The circle of union is reinforced by a running stitch (Fig. 12). The stomach is then sewed to the opening in the diaphragm, and the chest wall closed.

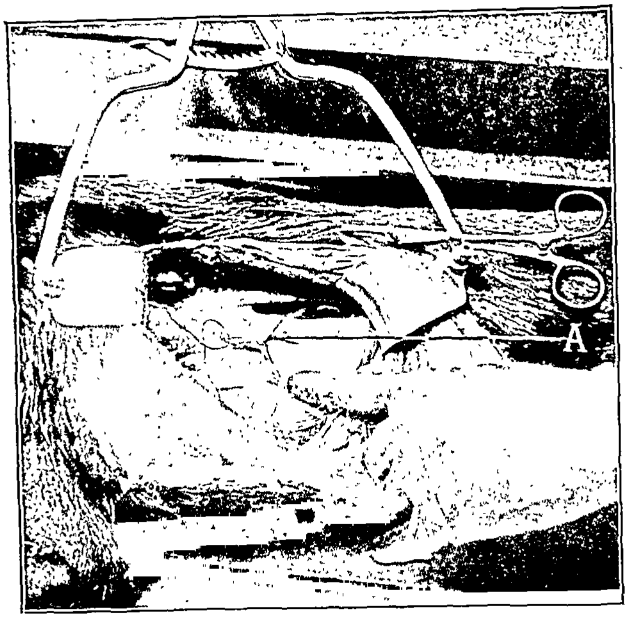

Fig. 6.—Anastomosis made by the button at A. It is being reinforced by a continuous Lembert suture around it.

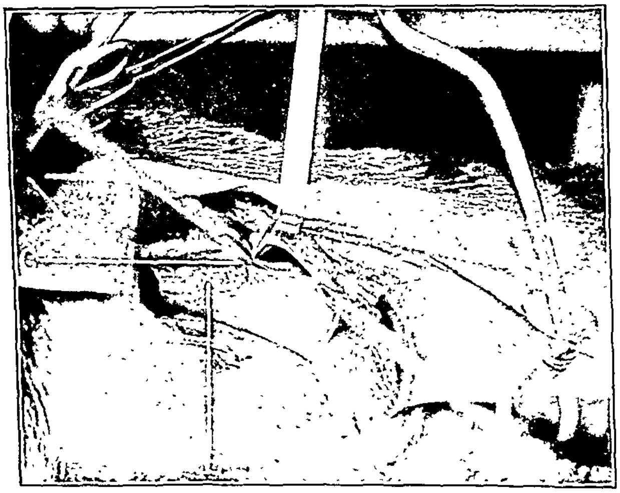

Fig. 8.—Opening behind the stomach into the peritoneal cavity. E, esophagus; artery clamp is holding the crus of the diaphragm C.

Our work has demonstrated that speed, absolute asepsis, and scrupulous care in the minimizing of trauma are essential to success in intrathoracic surgery. Even the exposure of the raw mucous membrane, a procedure which is done with impunity in the abdomen, is not devoid of danger in the thorax. It is, therefore, for the sake of diminishing trauma, and preserving greater asepsis that we have utilized a button in making the anastomosis. Our results have been decidedly better than they were by the suture method. We feel that the principles mentioned above explain why this is so. We have adopted the use of a button with some reluctance, because, for anastomotic purposes elsewhere, a suture method is preferable. We hope, from what Dr. Meyer has told us of his work in this field, that it may be accomplished.

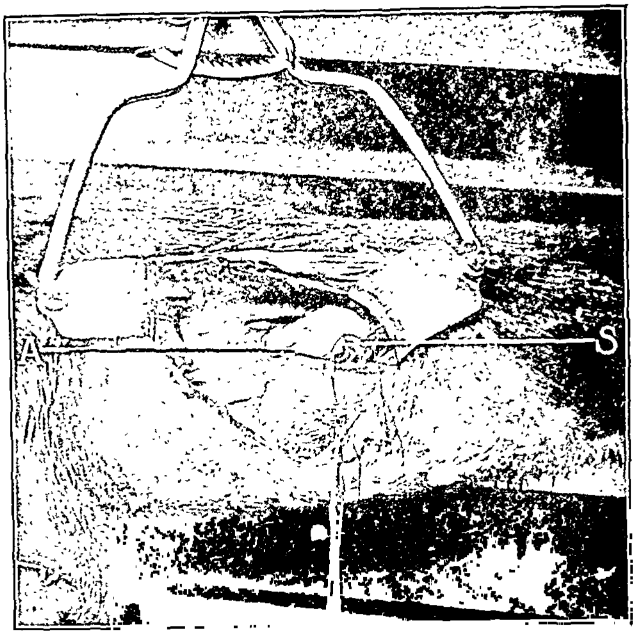

Fig. 7.—Anastomosis completed at A, and diaphragm being stitched to the stomach at S, for the purpose of preventing prolapse of any viscus into the chest.

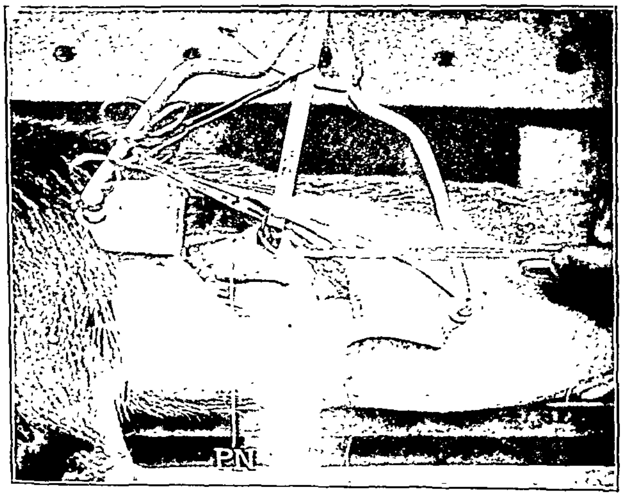

Fig. 9.—Passing of a double ligature around the gastrosplenic omentum and the attachment of diaphragm to esophagus. The left pneumogastric nerve with a diagonally communicating branch is shown at Pn.

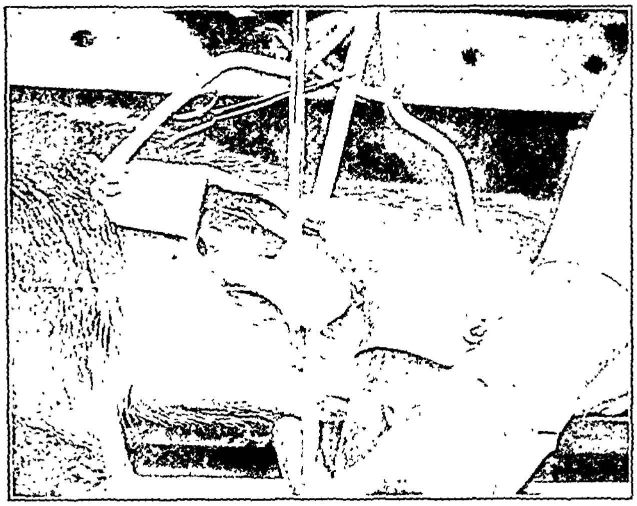

Fig. 10.—The gastro splenic and gastrohepatic omenta have been tied and the cardia has been drawn up into the chest. Two clamps are placed across it at C, preparatory to cutting it through with the cautery knife.

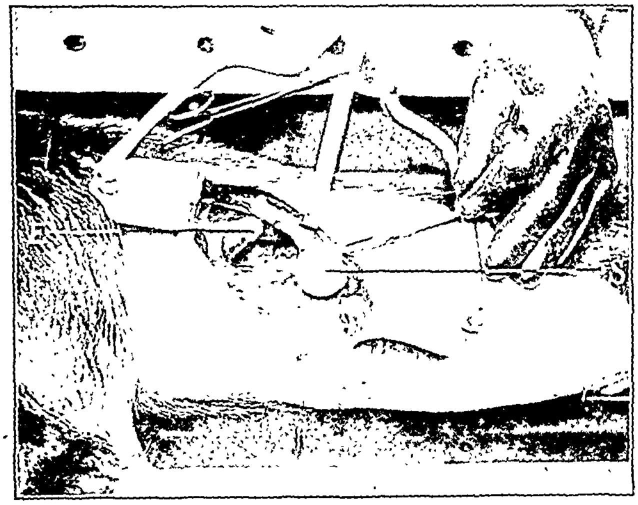

Fig. 11.—Stump of the esophagus, E, and the stomach, S, previously closed by a Lembert suture, and containing the female half of the button. Above the stump of the esophagus, and in its lumen, lies the male half of the button. These two portions are ready to press together to form the anastomosis.

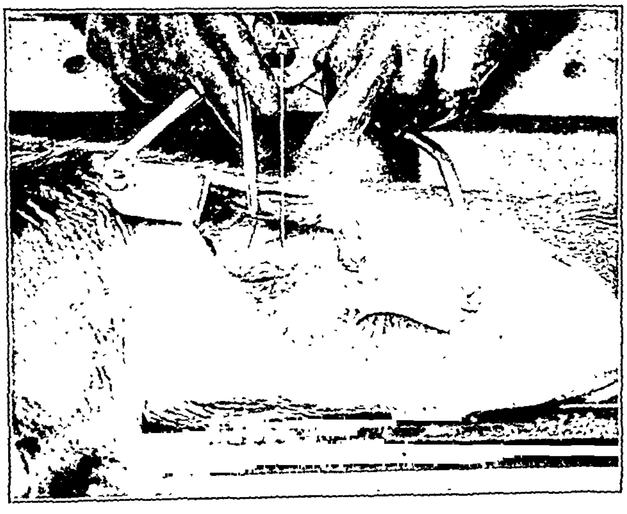

Fig. 12.—Anastomosis at A, made by pressing the two halves of the button together. A continuous silk suture is being passed around the point of anastomosis.

Even with our latest technic the results are far from satisfactory. We have, however, successfully accomplished four resections of the cardia and esophagus, and six lateral anastomoses of the stomach and esophagus without resection. Nevertheless, our work indicates that with a further improvement of technic the operation of the anastomosis with a resection can be accomplished without so great a mortality, and will eventually prove a procedure of promise. On the other hand, the operation of anastomosis of the esophagus with the stomach without a resection, under our present technic, is not accompanied with a high mortality.

PNEUMECTOMY WITH THE AID OF DIFFERENTIAL AIR PRESSURE: AN EXPERIMENTAL STUDY

THE NEW TYPE OF APPARATUS USED *

WILLY MEYER, M.D.
Professor of Surgery at the New York Post-Graduate Medical School and Hospital; *Attending Surgeon to the German Hospital*; Consulting Surgeon to the New York Skin and Cancer Hospital and New York Infirmary
NEW YORK

I. EXPERIMENTAL WORK IN EXCISING LOBES OF THE LUNG

Next to suturing stab and shot wounds of the lungs and extracting from the bronchi foreign bodies that have been located by the x-rays but cannot be removed by means of the bronchoscope, excision of a portion of the lung and amputation of one or more of its lobes (pneumectomy), have been rendered possible by the use of differential air pressure.

Resection of a lobe seems indicated when the greater part of it has become diseased, but its main bronchus cannot be properly reached and isolated. In the human being this condition is frequently encountered.

Extirpation of one or more pulmonary lobes, other more conservative methods having failed, will perhaps become the operation of choice in cases of serious destruction of the lung tissue by chronic inflammatory processes, and, of course, in the presence of new growths.

The success of the operation for total extirpation of the lung depends on the operators' ability to close the divided bronchus air-tight.

Various methods have been employed for this purpose, as follows:

1. One mass silk ligature around the bronchus and its vessels; amputation; cauterization of the mucosa of the stumps with pure phenol or the Paquelin cautery.
2. Elastic mass ligature around hilus; removal of lobe at second sitting (Lenhartz).
3. Ligature and division of main bronchus; remnant of lung tissue stitched over stump (Garré).
4. Isolation and temporary clamping of bronchus: curetting of the mucous membrane of the divided bronchus; tight silk ligature; second loose catgut ligature more centrally around bronchus (Friedrich).

A fifth method of extirpating the lung is developed below. It is original with myself as regards the treatment of the stump and was perfected in the course of operations on dogs at the Rockefeller Institute for Medical Research, New York, beginning the middle of November, 1908.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

In this work I had the able assistance of Dr. Martin Rehling, adjunct attending surgeon at the German Hospital of New York, who also took charge of the aftertreatment of the dogs operated on, and further of Dr. Edward Adams, instructor in surgery at the New York Post-Graduate Medical School and Hospital, for anesthesia. To both of them my sincere thanks are herewith again expressed.

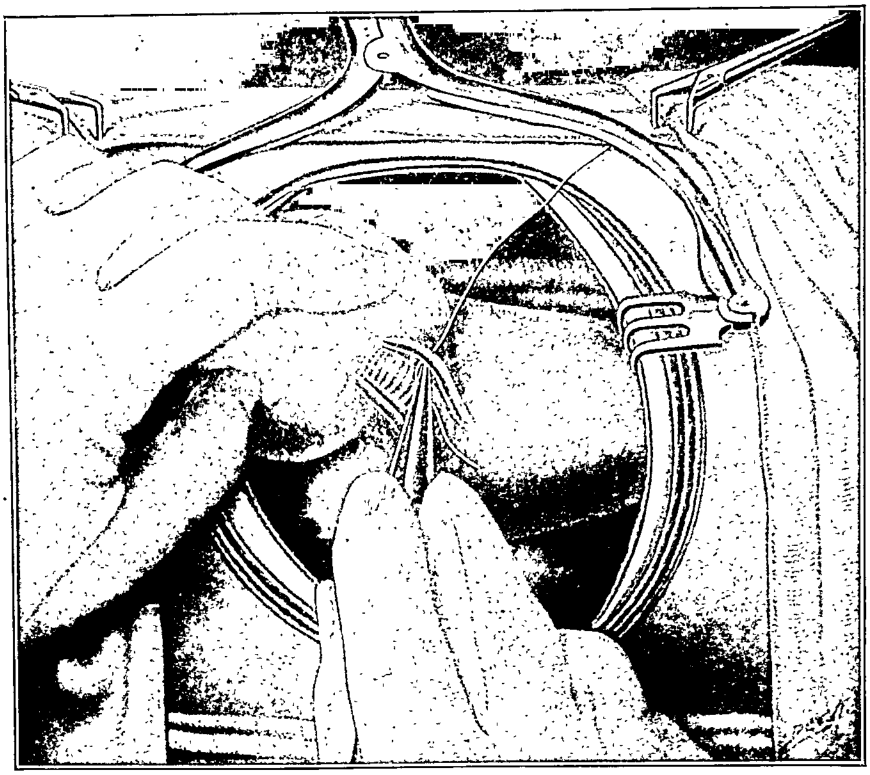

Fig. 1.—Intercostal incision in third or fourth left interspace. Rib-spreader in place. Descending aorta and portion of esophagus in background. Both hands covered with cotton gloves. Left hand pulls lobe of lung upward and palpates bronchus. Right hand pushes anatomic forceps between bronchus and its accompanying blood-vessels and draws silk thread through for ligature. Vessels then doubly ligated and cut through one after another.

After a few trials the mode of excision which is now pretty generally practiced in appendectomy was adopted as standard, viz.: isolation of the organ (here the bronchus); clamping and crushing; ligation and amputation; burying the stump; top sutures.

1. Isolating the Bronchus.—The lung is pulled forward with the left hand and its main bronchus palpated; with an anatomic forceps the spaces between accompanying vessels and bronchial wall are penetrated, one after the other, from the front backward; a silk thread is pushed between the blades of the forceps by the assistant and pulled through by the operator (Fig. 1). The vessel is tied close to the heart. Then by pulling on the first ligature, a second silk thread is passed through and tied distally. The vessel is then divided. This manner of securing the vessels in the depth of the thoracic cavity is preferable to using a Deschamps needle with a double thread. Two to four vessels have to be ligated according to anatomic findings, which vary much according to the early or late division of the pulmonary vessels. Now the bronchus is entirely freed; the loose connective tissue is pushed off with a gauze mop proximally and distally in order to have the bronchial stump as long as possible.

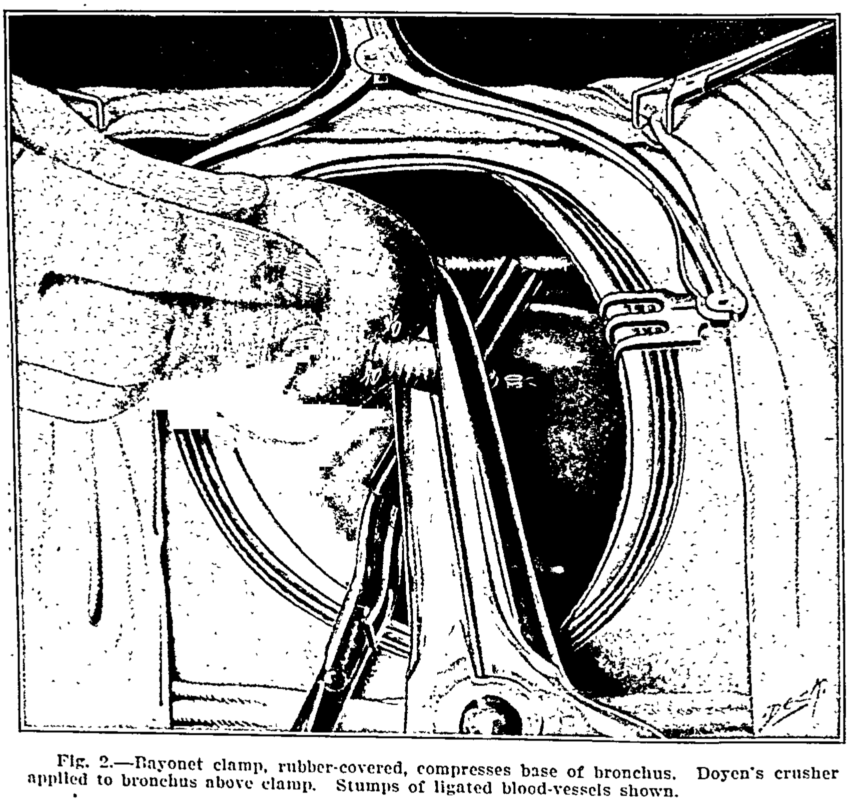

Fig. 2.—Bayonet clamp, rubber-covered, compresses base of bronchus. Doyen's crusher applied to bronchus above clamp. Stumps of ligated blood-vessels shown.

2. Clamping and Crushing.—A bayonet clamp is placed on the bronchus near to its base, its blades being covered with rubber tubing. Above it the bronchus is crushed,[1] usually with Doyen's large intestinal crusher (Fig. 2).

3. Ligation and Amputation.—The remaining fibrous sheath is ligated with silk, a clamp placed distally and the bronchus cut off (Fig. 3).

4. Burying the Stump; Top Sutures.—Before removing the bayonet clamp, or after, according to ease of access, the bronchus is secured on either side with a pointed forceps (Fig. 4). In order to accomplish that safely, a branch of the vagus nerve must

---

[1] The crusher should be an instrument the working of which can be fully controlled by the operator; it should always be applied with care, its nose pointing at right angle to the bronchus, catching the cartillages surrounding the bronchial tubes which have to be crushed in a line with their longitudinal axis; otherwise, a hole will be torn in the crushed portion.

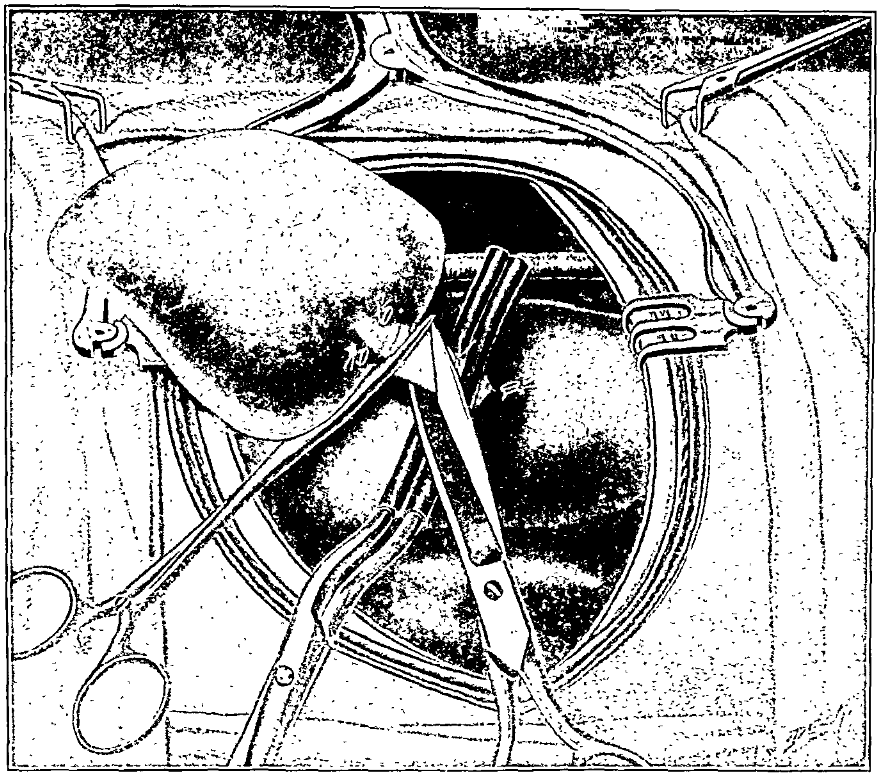

Fig. 3.—Crushed portion of bronchus ligated with silk about three-eighths to one-half inch above bayonet clamp. Strong artery clamp applied distally. Scissors divide crushed portion of bronchus between distal clamp and ligature.

often be pushed aside with a blunt instrument. Care should be exercised to avoid injuring the nerve. The two clamps are pulled on and the crushed part is pushed back into the lumen of the bronchus with anatomic forceps or tucker. Two to three top sutures (silk) draw the uncrushed part of the stump over the buried, crushed portion. The sutures must not include much tissue; they should not penetrate into the lumen of the bronchus. When tied, air-tight occlusion results (Fig. 6). If material is lacking, the pericardium can be hooked by the needle on one side of the bronchial stump and thus used to advantage for closure.

This method of burying the stump sometimes cannot be carried out; for instance, if the bronchus divides early, so that the ligature must close two lumina (Fig. 7, a). In that event an emergency method must be resorted to as follows: A second (mass) ligature is drawn around the stump by the assistant with an anatomic forceps in one hand and the crushed part of the bronchus pushed inward by him with the other hand. The operator then ties it firmly (Fig. 7, b). The ligature will, in most instances, grasp and then securely hold the buried part.

These are the two methods used by me in treating the stump. Both are practical, but the safer and more surgical one is the sewing of the uncrushed portion of the stump over the crushed portion, so as to form an air-tight cover for the same (Fig. 6, a, b, c).

The described method insures a permanently air-tight closure of the bronchial stump. The importance of such air-tight closure will be understood from the fact that leakage produces pneumothorax and, if the thoracic wound had already been closed, would result in a fatal issue. Should the stump be found to leak, such a condition becoming apparent through a rapidly increasing emphysema of the skin, the patient must promptly be put back under differential pressure, the thoracic cavity be reopened and the stump be made air-tight.

The next step in the operation is the closing of the thorax. In my paper[2] on esophagogastrostomy read last week before the American Surgical Association, it has been pointed out that in opening the thoracic cavity it is advisable to avoid resection of the ribs; closure of the wound is thereby simplified. The intercostal arteries are easily injured by the needle in closing the wound, if one or more ribs have been excised, unless a mass

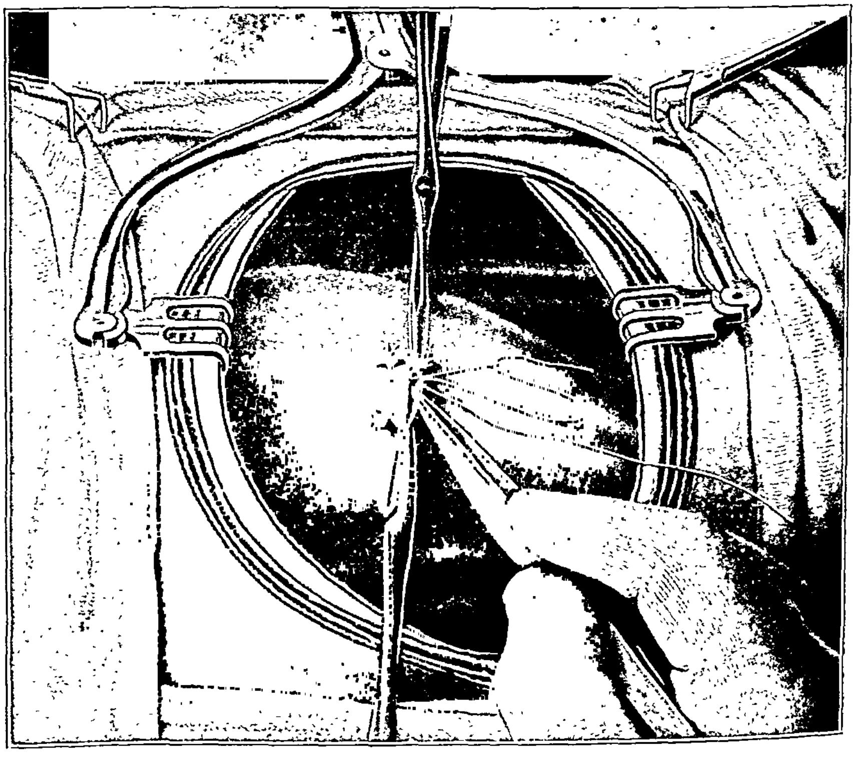

Fig. 4.—Stump of bronchus pulled forward with two pointed artery forceps. Crushed portion pushed inward with anatomic forceps (or tucker). One of the two or three required top sutures (silk) being laid.

---

[2] Meyer, W.: Esophagogastrostomy after Intrathoracic Resection of the Esophagus, Ann. Surg., July, 1909, L, 175.

ligature at the proximal end of the rib is made to surround the vessels. I prefer a long intercostal incision and then separate the ribs by a suitable rib-spreader. In closing the wound, two or three retention sutures with silk or chromicized gut surround the two ribs next to the incision.[3] Below, the needle enters close to the upper border of the rib which is to be surrounded, and above, it is made to hug the upper border of the rib adjacent to the incision (Fig. 5). The thoracic parietes are closed with continuous layer sutures of catgut. A few retention sutures of silk or catgut approximate the skin wound, which then is closed with great care, the needle always piercing the borders close to the wound to avoid overlapping. Aseptic gauze dressing completes the operation.

When the thorax is thus closed, the pleural cavity is, at first, full of air. With advancing cicatrization, this air is absorbed, the heart with the opposite lung is gradually pulled to the other side, the diaphragm rises and the thorax flattens somewhat. The cavity is thus gradually filled in. This process takes several weeks, if not months.

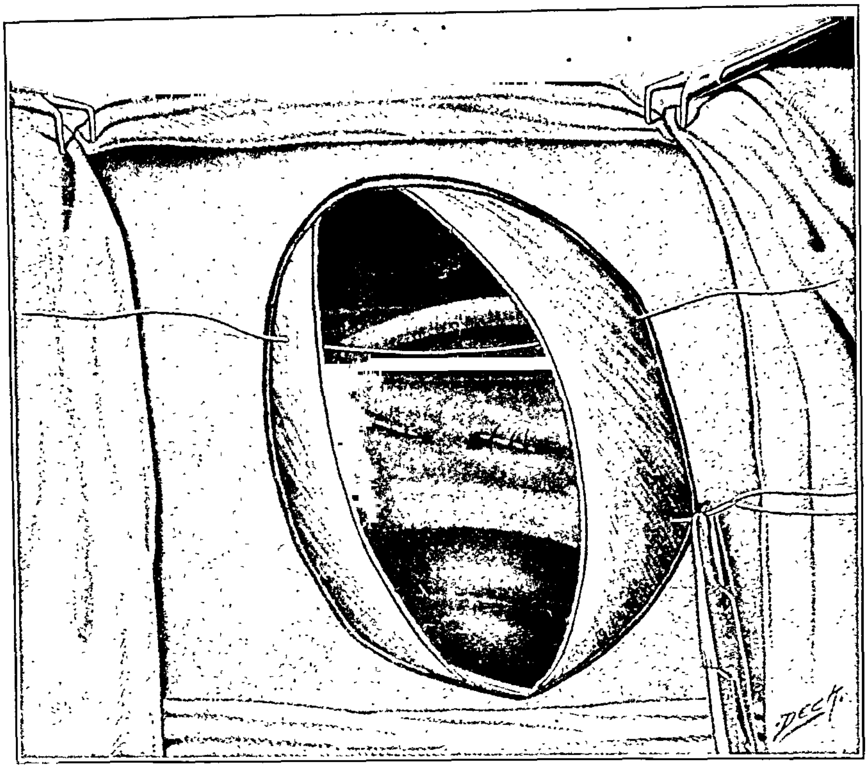

Fig. 5.—Sutured bronchial stumps in depth, shown diagrammatically. Esophagus crossed by aorta in background. One pericostal silk suture *in situ*, the second one being placed.

What takes the place of the removed lung in the interval? A logical conclusion would be to assume that a serous effusion sets in as soon as the air left in the empty pleural cavity has been absorbed. But such is not the case, according to Dr. F. C. Wood, of New York, pathologist to the German and St. Luke's hospitals, who kindly assisted in the investigation of this interesting question. His preliminary report, under date of May 26, 1909, on the first four dogs supplied him, is as follows:

PATHOLOGIC REPORT

The animals were bled from the femoral artery and then immediately injected through the same vessel with 4 per cent. formaldehyd. They were then frozen solid and sawn in that condition. The topography of the organs must, therefore, be absolutely normal.

Dog 1 (*Lab. No. 48*).—Terrier, white, fairly well nourished but of light bone; killed ten days after excision of the left lung. The thoracic wound was clean. There was considerable falling in of the lateral wall of the left chest, with restriction of motion of that side. The pleural cavity on the left side contained a small amount of clear serum.

On section, the right lung was found to fill the right side of the chest and to extend in its lower portion beyond the middle line. Anteriorly also it passed over the surface of the heart beyond the median line. The upper lobe curved forward to the left about 3 cm. beyond the middle line. Anteriorly the heart was in contact with the chest. Posteriorly the aorta and esophagus curved forward between the heart and the lateral chest wall so that there was a considerable space in the left pleural cavity still filled with air. There were no adhesions anywhere. The diaphragm on the left side had been pushed up about 2 cm. The stomach, though empty, was placed much higher than was usual, following the liver and diaphragm up toward the left pleural cavity. All the organs appeared normal. The bronchial stump was perfectly healed. The chest scar was clean and showed only as a slight thickening on the inner wall of the thorax.

Dog 2 (*Lab. No. 34*).—Foxhound, small white, rather thin, but with good muscle and bone; weight, 10.5 kilos. Operation, excision of left lung, March 19, 1909; killed April 1, 1909, thirteen days afterward.

No noticeable falling in of chest wall and no interference with respiratory movements.

Section in transverse plane showed right pleura large and filled with emphysematous lung. Heart pushed over about 2 cm. to left. Left pleura filled with air. No fluid in left pleura and no inflammation of walls of cavity beyond a slight reddening along the line of the intercostal incision into left pleura.

Dog 3 (*Lab. No. 33*).—Terrier, brown, in good condition, but thin and light-boned. Left lung excised March 16, 1909; killed April 3, 1909, eighteen days after operation.

When alive the thorax on the side from which the lung was removed showed some falling in and restriction of movement in breathing.

On section, the left pleural cavity was closed, but the leaves of the pleura were not adherent. There was no inflammatory exudate. The right lung had expanded, following the heart to the left. The lower lobe passed completely behind the heart over to the left, and appeared to the left of the ventricle. The site of the bronchial stump can scarcely be seen.

Dog 4.—Terrier, white with black and brown markings, very powerful muscles and bones. Dog in very good condition. Left lung excised March 9, 1909; killed April 8, 1909, thirty days later.

While the animal was alive no falling in of the thorax or restriction of movements was noticed.

On section, the heart was found to be slightly displaced to the left and followed by the right lung. The left pleural cavity was but slightly smaller than normal and was filled with air. There was no fluid in the pleura and no evidence of inflammation. The bronchial stump projected about 2 mm. from the mediastinal wall, and the ligatures were still present.

---

[3] This method suffices in animal experimentation. When operating on human beings, Friedrich drills a hole into the lower rib, passes the ligature through the same, and then surrounds the adjacent upper rib. In view of the fact that the thin fascial parts of the thoracic wall, when sutured, tend to necrosis, thus interfering with primary union later on, it seems advisable to use in place of silk, chromicized catgut for these sutures. It does not have to be extracted.

It is astonishing how well dogs stand entire removal of the lung on one side. Often they were on their feet in less than an hour after the operation, as soon as the effect of the hypodermic injection of morphin had worn off, which was administered at the time of putting on the dressing at the close of the operation.

The remarkable ability of the lung to continue performing its function even in the face of a far-reaching, though gradual, destruction of its tissues, as in tuberculosis, is well known. Research by means of differential pressure has now shown that such destruction of lung tissue is equally well borne when it occurs suddenly, i. e., if one or more lobes are removed with the knife.

The method for such sudden removal, described above, is a reasonably safe procedure in dogs and so effective that its trial on human beings appears justified in cases in which excision of the lung is indicated, with this difference, however, that in the human being the first branches of the main bronchus *take the place* of the main bronchus of the dog (Friedrich).

As proof of the effectiveness of the method the statistics follow below of my results obtained with it at the Rockefeller Institute in the course of the last six months.

Twenty-one total pneumectomies were performed, 18 on the left and 3 on the right side. Of the 18 dogs on which the left-sided operation was performed, 15 recovered and 3 died. The cause of death in one case was a small gauze mop left in the chest, and in the other two cases pneumothorax, which was due in one instance to a leaky stump and in the other to the reopening of the inner angle of the sutured wound. Of the 3 dogs on which right-sided pneumectomies were performed, 2 recovered and 1 died, death being due to distemper.

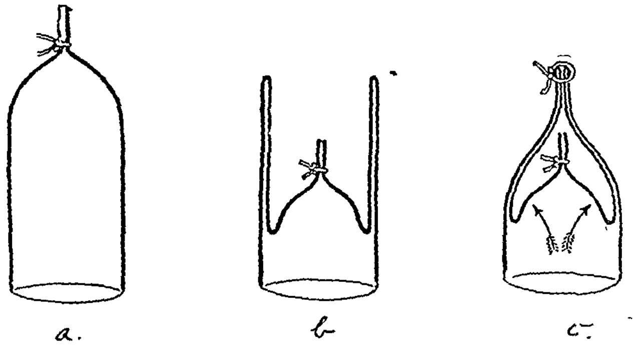

Fig. 6.—Diagram: stump and crushed portion of bronchus (a) tied; (b) pushed inward; (c) sutured. Arrows indicate direction of intrabronchial air-pressure, which makes bronchus air-tight against itself. Safety of occlusion increases with increasing air-pressure.

Thus of 21 total excisions of one side of the lung we had 17 (81 per cent.) recoveries and 4 deaths.

Removal of one or more lobes of one lung was done 6 times. Of these dogs 5 (100 per cent.) recovered and 1 died, death occurring in the course of the operation from the anesthetic.

Summing up, I had in my work, as far as the finished excision of the lung is concerned, in 26 cases, 22 recoveries (84.6 per cent.). At one time an uninterrupted series of 12 dogs recovered without a single death. Usually the wound healed under one dressing.

These satisfactory results I attribute to the rigid asepsis and the method of operation employed, also to the safe and reliable working of the new "differential pressure apparatus," by means of which all the operations were performed.

It is described in the second part of this paper.

II. THE NEW AMERICAN-BUILT APPARATUS FOR THORACIC SURGERY

We owe it to the work of Sauerbruch and Brauer that the thoracic cavity has been definitely opened to surgery. There now remains no nook, no corner of the human body to which the knife cannot be applied with safety.

Operations on the organs within the thoracic cavity, principally the lungs, esophagus and heart, have been done prior to the research work of those investigators. Especially the heart has had an exceptional position, inasmuch as an osteoplastic operation on the thoracic wall permits the surgeon to reach it and its pericardial sac without injury to the pleural cavity. Still, such injury could not always be avoided, nor was a safe operative attack on the lungs and esophagus, without the presence of adhesions between costal and pulmonary pleura, possible before 1904.

The physiologists, it is true, had solved the problem long ago in their laboratory work on animals. With a cannula tied in the incised trachea, or later with an intubation tube, air was rhythmically forced into the lungs by bellows and artificial respiration thus kept up as long as needed (Fell-O'Dwyer and others).

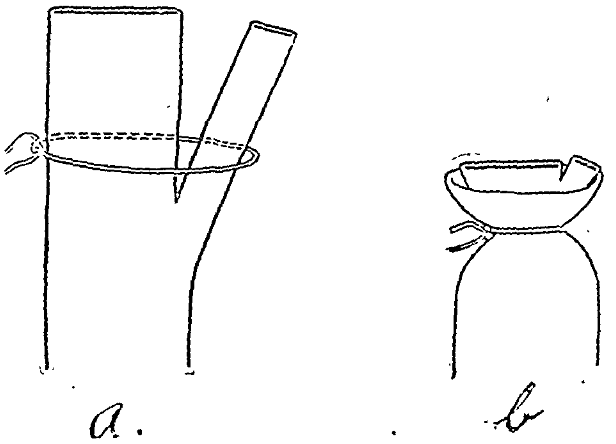

Fig. 7.—Diagram: bronchus short and dividing early; (a) ligature of crushed main bronchus and branch; (b) crushed portion being thicker than lumen of bronchus, the complete pushing in is not feasible. Mass ligature around stump and crushed part.

But with such devices the surgeon could not be satisfied for regular operative work on sick human beings. His requirements differ from those of the physiologists. He must be enabled to do operations within the thorax as safely as in other parts of the body, at least so far as general anesthesia with its possible sequelæ and accidents is concerned. He should not be obliged to put a cannula into the trachea, either through the mouth or directly through a tracheal incision to produce anesthesia. The head and mouth of the patient must be as unincumbered and within as easy reach of the narcotizer in thoracic surgery as in other operative work, *while an* acute pneumothorax must be avoided, that stumbling-block which, up to the beginning of this century, practically excluded the lungs and intrathoracic portion of the esophagus from the domain of operative surgery. The requirements of the surgeon are *filled by differential* air pressure apparatus.

I have been interested in differential pressure surgical work from its inception, having been brought in close touch with it, while in Europe in 1904, and seeing at that time an operation performed in the just completed first differential pressure chamber ever built.[4]

---

[4] Ann. Surg., 1905, xli, 667.

But there remained in that chamber as well as in all those built later on the same general lines considerable scope for improvement.

The European negative pressure chambers being constructed entirely of metal, are reverberating and through their pipes connecting with the pump cylinder all the noises occurring from valves and otherwise in the pump are directly transmitted to the chamber. Surgeon and anesthetizer are separated by a solid wall and cannot hear each other speak; for communication a telephone is provided, but the noise in the chamber makes it almost useless. Again, the anesthetizer can look into the chamber; but the surgeon cannot see the face of the patient, which is hidden from his view by a metal casing. Neither surgeon nor the assistants have sufficient elbow-room, and there is no space for an assistant to the left of the surgeon. No provision has been made against break-down of power. As placed, the large European differential pressure chambers can be used for negative pressure only.

All the other types of European apparatus are constructed for positive pressure only. They are distinctly inferior to the above-mentioned negative apparatus, inasmuch as with all of them occasions arise which necessitate the interruption of the differential pressure during anesthesia, the Engelken type of apparatus perhaps excepted; but the latter has not only all the before-mentioned disadvantages of the negative pressure chamber, but also the additional fault that the anesthetizer is not permitted to concentrate his attention exclusively on the patient, he having to take care also of the pressure-regulating valve and of the telephone.

In the Brauer as well as in the Engelken type of apparatus the anesthetizer's position during the operation is rather uncomfortable, and in the Brauer type especially the proper handling of the patient under anesthesia is a difficult matter.

Apparatus combining intubation and masks appears so manifestly inadequate and dangerous for every-day surgery that it cannot deserve preference over apparatus leaving the mouth of the patient unincumbered. Yet this kind of apparatus, too, and the ingenious devices of Tiegel, Brat-Schmieden, Karewski, also Seidel's apparatus for after-treatment, will find their place.

In the spring of 1908, when I wished to acquire apparatus for intrathoracic operations, only that invented and manufactured in Europe was publicly known. A careful canvass of the whole field showed that the then existing apparatus was of two general types: one working from atmospheric pressure downward (negative pressure), the other one from atmospheric pressure upward (positive pressure).

But there was none working both ways, and it was just such apparatus that I wanted. I decided to build it myself and, moreover, to build it in this country. I got in touch with my brother, Julius Meyer, an engineer by profession, and succeeded in interesting him in the subject. Together we constructed a chamber for positive and negative differential pressure. It comprises an outer negative pressure chamber, the operating room (Fig. 8), and within the same a positive pressure chamber, the anesthetizer's room (Fig. 9), by means of which combination it is possible to operate either under negative differential pressure or under positive differential pressure, under a combination of the two or under a change from one to the other in the same operation.

The advantage of combining two chambers to form one apparatus becomes apparent also in the feature that the operating table remains in the same location under whatever pressure the operation is performed, and that the moving about of the operating-table from inside to outside, necessary with the large European chambers, if their pressure were changed from negative to positive, or *vice versa*, is here entirely avoided. Further, there is in the new chamber ample elbow-room for the surgeon and his assistant and for an assistant to the left of the surgeon, obtained by means of a projecting head-box. The opening in the latter is closed by a rubber collar, which can be adapted to the size of the neck, and the bulging of the collar is prevented by guillotine shutters. The operator can see the face of the patient and the anesthetizer can see the body of the patient. For the latter purpose a mirror is provided, but the anesthetizer cannot see directly the field of operation proper, so that his attention is not distracted from the anesthesia, but must be given entirely and exclusively to it. The anesthetizer has the face of the patient before him, as is customary in ordinary operations, because he and his assistant are enclosed, together with the head of the patient, in the positive differential pressure chamber. The head of the patient is adjustably suspended. The anesthetizing chamber is so large that there is ample space for oxygen apparatus; it has an air-lock providing access or egress while the pressure is on and without interruption thereof.

No air-lock is needed for the operating-chamber. The pressure in the latter can at any time be raised from negative to atmospheric pressure while the differential pressure required for the operation is being maintained without interruption, so that the door of the operating-chamber leading to outside can then be opened.

The plant is so constructed that a triple reserve is provided in case of break-down. There are two independently driven sets of pumps, one for pressure and one for vacuum, so that in case of any mishap to one unit an immediate change can be made from one kind of differential pressure to the other; in case of accidents to both units a hand-pump is provided, by means of which to maintain the positive differential pressure in the anesthetizing chamber. The motors run at constant speed. The variation of the air-pressure in the chambers is effected by the manipulation of two air-valves, which are set by hand to the desired gauge readings, a matter so simple that mistakes are excluded. The valve is not of the water-column type, but simply a cock. The chamber is of knock-down construction and transportable. The structure in its entirety is very simple and there is nothing in it to get out of order.

The constructive feature distinguishing these chambers from others is the use of two different materials, metal and a fabric, for the obtaining of its two requirements, strength and tightness. Iron can offer the needed resistance to air-pressure; balloon material is air-tight. By the combination of the two into one air-tight structure, the ironwork profits to the extent that it can be treated as a light open framework, easily put together and just as readily taken apart, and that the shops building it will find in the specifications no requirement foreign to every-day structural iron routine; on the other hand, the balloon material profits to the extent that it does not have to sustain the air-pressure, that its distortion into a bulging ball is prevented, and that by the iron frame it is kept to the desired shape. In the positive pressure chamber (Fig. 10) the fabric is arranged inside of the metal frame and in the negative pressure chamber outside of it (Figs. 8 and 9).

As stated above, all the heretofore constructed apparatus can be divided into two groups, one working from atmospheric pressure downward, and one working from atmospheric pressure upward. The new chamber belongs to neither group. It is *sui generis*. In constructing it the aim has been to overcome and remove the limitation of differential pressure chambers to atmospheric pressure as the fixed basis at one end of the difference in pressure, and to enable the establishing of the basis anywhere above or below or at atmospheric pressure at will. This was accomplished by combining two differential chambers to form one apparatus.

In combining two rooms to form one apparatus the following modifications are possible:

1. The rooms may be separate.
2. The rooms may have one corner in common.
3. The rooms may have one wall in common.

In all of these cases the two rooms can be either outside of each other or one inside of the other one.

4. Two rooms may be one partly outside and partly inside of the other one.

For the purpose in hand the combination of two separate rooms, one inside of the other one, was selected.

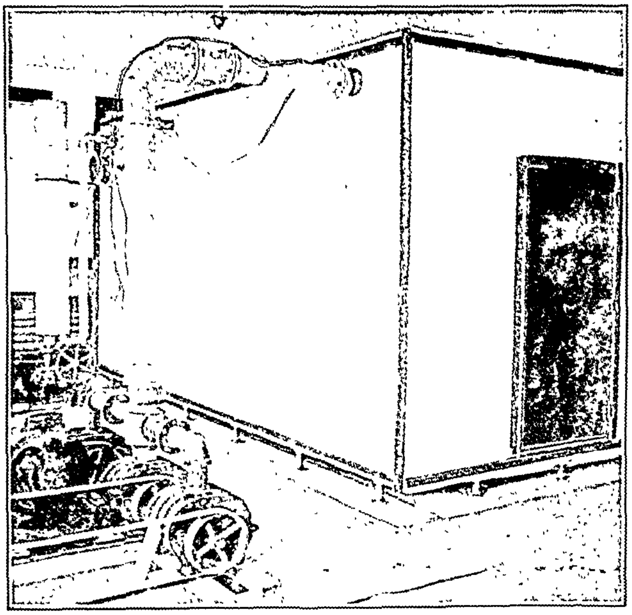

Fig. 8.—Outside view of universal differential pressure chamber (first experiment).

But several of the other modifications will have their use on occasion.

As regards the air-pressure in these rooms the following combinations can be made.

1. The pressures in both chambers deviate in the same direction from open air:
   - A. Inner positive chamber combined with outer positive chamber.
   - B. Inner negative chamber combined with outer negative chamber.
2. The pressure in both chambers deviate in opposite directions from open air:
   - C. Inner positive chamber combined with outer negative chamber.
   - D. Inner negative chamber combined with outer positive chamber.

Positive chamber in negative chamber (2-C) is the combination which I have built and which I have in use at the Rockefeller Institute in New York. It was selected for construction, first, because it enables the nearest approach to operating in open air by building up the differential pressure of half positive and half negative pressure; second, because the anesthetizing-room can be used independently as a positive pressure chamber, and, third, because the chamber can readily be transformed into negative chamber in negative chamber (1-B) by simply reversing the motor of the pump that ventilates the anesthetizing room, whereby the pump is converted from a blower into a suction pump. If the valves are now set to produce a higher rarefication of the air in the operating-chamber than in the anesthetizing room, the latter remains, relatively speaking, a pressure chamber, and, by maintaining the proper differential, the thorax can safely be opened with negative pressure over the mouth as well as over the open thorax. On May 15, 1909, an operation was performed under such conditions with a local barometric pressure of 760 mm. Hg. and 744 mm. over the open thorax and 750 mm. over the mouth of the patient—which is equivalent to doing the operation at a higher altitude.

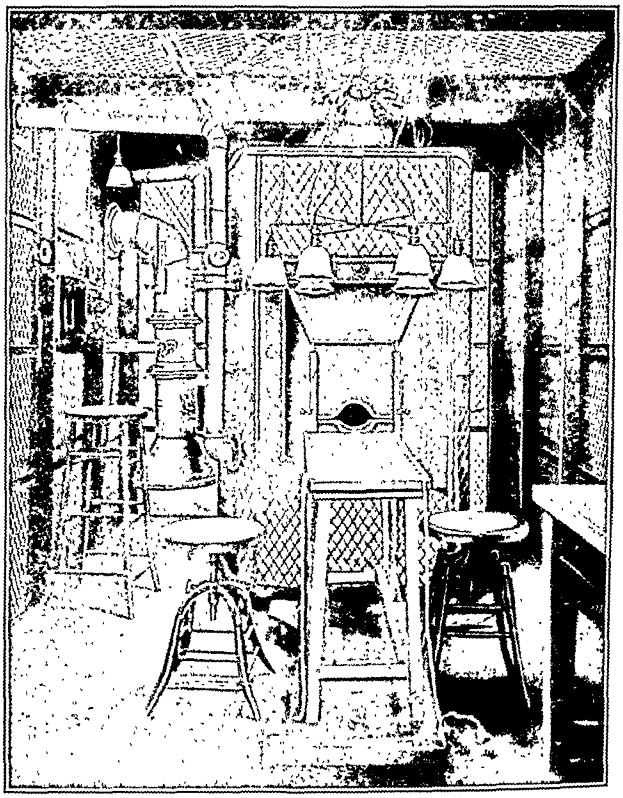

Fig 9.—Inside view of universal differential pressure chamber (first experiment).

This kind of work may become of importance in operating on patients afflicted with pulmonary tuberculosis. Consumptives are sent to higher altitudes for treatment: there may, therefore, be something in lifting a patient during the operation to an altitude many hundred feet above the one where the operation actually takes place and in lifting him frequently back to that altitude in the after-treatment. It may be that internists, too, will find such chambers useful in the treatment of pulmonary diseases.

By merely ventilating the outer room at atmospheric pressure and putting the inner room under increased pressure the two combined chambers become simply a positive differential pressure apparatus.

Thus in this particular combination of rooms an operation can be performed under all of the following conditions:

1. Under positive differential pressure.
2. Under negative differential pressure.
3. Under part positive, part negative differential pressure.
4. Under a gradual change from positive to negative differential pressure, and *vice versa*.
5. Under a repeated change from positive to negative differential pressure, and *vice versa*.
6. Under negative differential pressure at an altitude above sea level higher than that of the place where the operation is performed.
7. Under negative differential pressure same as 6, but at gradually or repeatedly changing altitudes.

The foregoing enumeration comprises all the various conditions under which differential pressure operations can occur, and this apparatus is, therefore, named a "universal differential pressure chamber." In contradistinction to it the narcotizing-room, when independently used, is named a "positive differential pressure chamber," because it must always and under all conditions have a higher pressure inside than outside of it.

The combination, inner positive chamber in outer positive chamber (1-A), is not likely to be used. Its effect would be equivalent to lowering the open thorax of the patient into a shaft below the surface of the ground and depressing the mouth of the patient still further.

On the other hand, the remaining combination, negative chamber in positive chamber (2-D) is again of importance, though not in thoracic surgery, because negative pressure at the mouth and positive pressure at the open thorax would accentuate the pneumothorax. But in brain surgery this combination of chambers will find its place. By means of it the blood can be drawn away from the head and by varying the pressure we can control the quantity of blood thus temporarily withdrawn from circulating through the heart. In this combination the patient's body is put into the inner room.

The positive differential pressure chamber described in this paper (Fig. 10) was built to withstand hard usage. It has been put up and knocked down many times. It was first erected in the iron works, then knocked down, transported to another factory for completion and assembling with parts constructed elsewhere. It was there erected and tested, then knocked down and transported to the Rockefeller Institute; there erected, used in operations on dogs, knocked down and transported to the German Hospital in New York; there erected, used in operations on patients, knocked down and transported to Philadelphia; there erected in the Jefferson Medical College Hospital for demonstration before the American Surgical Association, knocked down and transported back to the German Hospital in New York, and on arrival there went together with as little trouble as it did when first completed.

A structure has to be strong and solid in all its parts to endure such treatment without becoming dented and twisted and thereby troublesome and expensive by needed repairs. A chamber built to remain at one place may be built lighter. But the rough handling that this German Hospital positive differential pressure chamber in its many migrations was subjected to by truckmen and on the railroad without suffering damage thereby proves its fitness for use in war, and it was partly with the object of testing it for military requirements and under something like war conditions that this chamber was so many times knocked down, carted from place to place and re-erected. On an average it took one man and a helper about one hour to knock it down and the same number of men about four hours to erect it again ready for use. The time can probably be reduced should the work be done by military men of the sanitary corps, specially drilled for the purpose.

Mention should not be omitted of the fact that with the positive differential chamber artificial respiration was produced in a case of collapse by rhythmic movements of the valve handle, increasing the pressure quickly to 12 mm. Hg. and lowering it again to atmospheric pressure.

The chambers are cleaned by using the suction pumps as a vacuum cleaner, by means of which such dust as may be there is removed from the wire frames of walls and ceiling. The floor of the negative chamber is solid and so constructed that it can be scrubbed. In the final construction of the chamber its walls and ceiling will be similarly arranged.

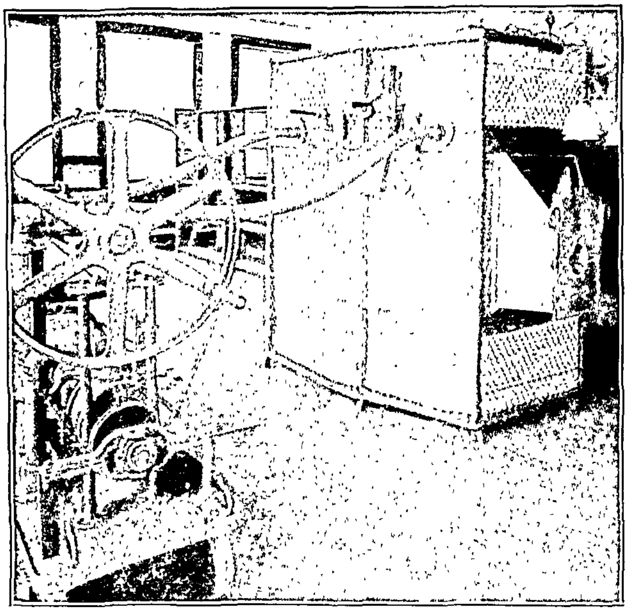

Fig. 10.—Positive differential pressure chamber (first experiment).

Formalin vapors are used for disinfection, which are then ventilated off by the pumps.

When I began to use the chambers, the question arose in my mind: How far can we go in exposing ourselves to such positive and negative pressures? Where is the danger-line? Inquiry developed the fact that even should the negative chamber be exhausted to a differential pressure of 50 mm. Hg., thus being strained to the limit of its capacity, we would, in exposing ourselves to that differential, still be within the limits of our possible every-day experience, as barometric fluctuations of 50 mm. Hg. are nothing unusual in our climate.

On this subject a letter was received under date of Jan. 7, 1909, from the central office of the U. S. Weather Bureau at Washington, D. C., which reads in part:

> The height corresponding to a change of pressure from 760 mm. to 710 mm. varies with different temperatures of the air column. The change of 50 mm. pressure at sea level with a mean temperature of 0 C. would correspond to an elevation of 1,786 feet, at 15 C. to 1,881 feet, and at 30 C. to 1,978 feet. The range of the barometer at New York is more than 50 mm.

The differential pressures used in thoracic surgery seldom exceed 7 or 8 mm. Hg., corresponding to a difference in altitude between 250 and 300 feet; that is to say, the patient's mouth is lowered about 300 feet below his opened thorax. The anesthetizer, however, as well as the surgeon and his staff are not under differential pressure at all; their entire bodies are under one pressure only. Eight mm. Hg. is equivalent to a pressure of about one-sixth of a pound per square inch. In caisson foundations for bridges and tall buildings workingmen are required sometimes to work for hours at a time under air pressures of thirty and more pounds to the square inch, without detriment to their constitutions, which indicates that we are far removed from danger when working in our chamber under positive pressure. As to vacuum I have no such records to offer. We ourselves have been frequently under 16 mm. Hg. negative pressure, drawing the pressure down rapidly, without any perceptible detriment, though feeling a slight pressure on the ear-drums, which, however, disappeared after swallowing once or twice. Hints in this direction can probably be obtained by looking up, for instance, the practice with pneumatic chambers used in bathing institutions; but time has been lacking to do that for this paper.

Again, if the differential pressure in the universal chamber is composed of part vacuum and part pressure, only the patient is exposed to the full differential, while all others are exposed only to the component fractions thereof, the anesthetizer to the positive fraction and the surgeon and those with him to the negative fraction, which still more reduces any possibility of detrimental effects on the users of the chamber.

It was to be supposed that a differential pressure composed of part positive and part negative pressure would act the same as one of equal magnitude but entirely positive or entirely negative. After several operations performed under such conditions, it can now be stated that it does act the same, at least as far as keeping the lungs inflated is concerned. But there seems to be this difference, that abdominal and thoracic breathing come more or less into play according to the variation of the components. Observations along this line are still in progress. Further, there seems to be a difference in the effect of the narcotic under positive and negative pressure. With increasing vacuum component the anesthesia apparently becomes deeper and it becomes less deep when the positive pressure component is increased, which is equivalent to stating that a smaller amount of the narcotic is required under negative pressure to produce a satisfactory anesthesia.

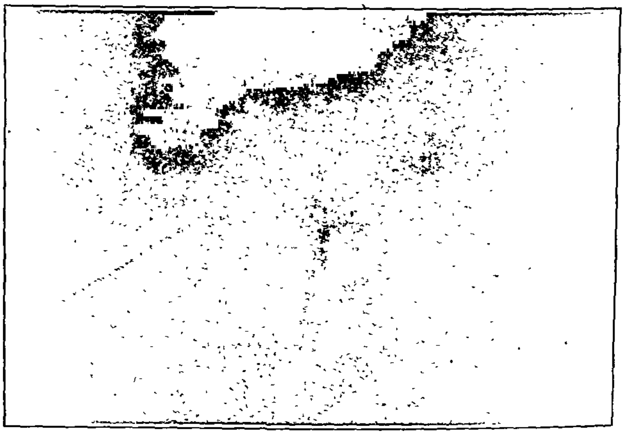
In conclusion, a word about the history of the new apparatus. The studying up, designing and constructing of these chambers has occupied my brother and myself since May of last year, my brother devoting himself entirely to the matter. The work of construction was begun in November of last year. A start was made with the smaller and less expensive apparatus on which to make our mistakes and such blunders as are liable to happen when plodding into the unknown. Therefore, the building of a positive differential chamber was first attacked. It was tested on December 23, was found to work all right and was first used in an operation at the Rockefeller Institute on January 8 of this year. It came up to requirements in every way, so much so that the building of a large universal differential chamber was immediately taken in hand.

It was not carried to completion as expeditiously as the first one, for several reasons. The vital question of dimensions was an open one for a long time, because the finding of the best adapted rooms in the German Hospital, where the chamber was to be placed, offered considerable difficulty. Then, of course, the thing had first to be invented; the many roads leading to Rome had to be gone over, all the many details had to be worked out and tried out and everything had to be boiled down from the complicated to a condition of extreme simplicity in order to make it trouble-proof. Further delays occurred in manufacturing the apparatus. There is practically nothing in the chamber that is standard; almost everything is special and had to be made to order. Difficulty was encountered to find manufacturers at all willing to let such special work interfere with their routine business.

Finally, on May 7, the universal chamber stood completed in the Rockefeller Institute; and a lung extirpation was performed therein on that day with the following gauge record:

Time.		Pressure MM. Hg.		Time.		Pressure MM. Hg.	
Hr.	Min.	Negative.	Positive.	Hr.	Min.	Negative.	Positive.
4	27	0	0	4	44	0	6
..	31	6	0	..	56	1	5
..	32	5	1	..	57	2	4
..	34	3	3	..	58	3	3
..	37	4	2	..	59	4	2
..	41	3	3	5	00	5	1
..	42	2	4	..	03	6	0
..	43	1	5	..	10	0	0

Instructions had been given to the man at the valves to make frequent changes in the pressure components at short intervals, so that the effect of the changes might be observed. At 4 hours 44 minutes, when atmospheric pressure prevailed in the operating-chamber, the door to outside was opened and one of the guests left, the operation meanwhile going on without interruption. It will be remembered that the negative chamber has no airlock. During the next following operation the house telephone suddenly rang outside the chamber, while the gauge recorded 6 mm. Hg. vacuum inside. The vacuum was raised to atmospheric pressure, the door opened, the telephone attended to, the door closed and the vacuum of 6 mm. restored, all without interruption of the operation or disturbance of the differential pressure.



Needle in position for injection of middle branch. Case 46.

Illustrating Article by Dr. Patrick

As stated above, this is no longer a Sauerbruch chamber or a Brauer apparatus. It goes beyond what they conceived. Neither of them can build up the differential of part positive and part negative pressure or go from positive to negative pressure, or *vice versa,* in the course of the same operation. Even in physiologic work, investigators have heretofore never put a dog on which they experimented, first under positive and then under negative differential pressure in the same apparatus. It was always one dog under positive and another under negative differential pressure. An element of uncertainty is thereby carried into their conclusions regarding the relative merit of the two kinds of pressure.

This American-built apparatus enables us for the first time to study the behavior of one and the same animal during one and the same operation, under both kinds of differential pressure, under a change from one to the other, and also under a change of the altitude above sea level. What is more important, it enables us also to study pathologic conditions of man in the same thorough manner, excluding all guesswork, and to find the indications for the pressures best adapted to and safest to use in the many varying degrees of related diseases of human kind.

[Editor's Note: The three preceding articles are part of a Symposium on Thoracic Surgery which will be concluded next week by the articles of Drs. Powers and Beck and the discussion.]

SEVENTY-FIVE CASES OF TRIFACIAL NEURALGIA TREATED BY DEEP INJECTIONS OF ALCOHOL *

HUGH T. PATRICK, M.D.
Clinical Professor of Nervous and Mental Diseases, Northwestern University Medical School
CHICAGO

Two years ago I reported sixteen cases of trifacial neuralgia treated by deep injections of alcohol,[1] and four months later I briefly reported seven additional cases.[2] The method was new, scarcely known in this country; and, further than the fact that injections into the nerve instantly stopped the pain, not many definite statements could be made either for or against it, although it promised well. Even now it is so unfamiliar to the medical public that, having employed it for nearly three years, I feel that my results should be reported.

Needless to say, by trifacial neuralgia I mean neuralgia of one or more branches of the fifth or trifacial nerve; not migraine, which often is called neuralgic headache; not sinus disease; not anything but classical tic douloureux. That the patients with this malady suffer horribly is known to all. That a treatment simple, effective and devoid of danger is a great desideratum needs no emphasis. While the deep injection method is by no means ideal, it is relatively simple, it certainly is effective in relieving the pain, and it is practically free from serious danger. As a radical cure it can not compare with complete removal of the Gasserian ganglion, but, except in a very few and peculiarly skilled hands, the latter operation is difficult and dangerous—very dangerous, indeed, for the majority of operators. To mention treatment by drugs, electricity, heat, etc., is to note the ultimate futility of these measures in the vast preponderance of cases. The various peripheral operations on the several branches of the nerve, including the Abbé operation of dividing them peripheral to the ganglion, have all met a measure of success, but all require an anesthetic, and those which are neither difficult nor dangerous generally give relief for only a brief period. Concerning the deep injections of alcohol I have no thesis to maintain. I wish simply to state my results and to add a few hints, the fruit of experience.

To redescribe the technic[3] seems unnecessary, but I may state that the injections are made with a straight needle about 10 cm. long, 1.5 mm. thick and fitted with a stylet or obturator, the blunt end of which is flush with the needle-point. The sharp point is used to puncture the skin, after which the stylet is pushed home, making a blunt instrument for the remainder of the penetration. Both Brissaud and Sicard, and Lévy and Baudouin have discarded the stylet, using a more slender and sharp needle. I have tried the latter, but prefer the former. The needle is introduced at the lower border of the zygoma, the object being to reach the inferior maxillary division of the nerve at its emergence from the foramen ovale (about 4 cm. deep) and the superior maxillary as it leaves the foramen rotundum (about 5 cm. deep). Deep injections for the supraorbital branch I have abandoned as being too hazardous. When an injection of this branch is needed, which is not very often, I use a "peripheral" injection at the supraorbital notch. In a few cases I have also used a "peripheral" injection at the infraorbital foramen.

The solution used is about 85 per cent. alcohol (not absolute) with four grains of cocain to the ounce. Of this, about 2 c.c. are introduced each time. Morphin and chloroform, formerly used in the solution, I have abandoned, and I also have stopped using 75 per cent. alcohol for the first injection.

As before intimated, this paper is simply a record of results, but tabular statements and summaries sometimes conceal almost as much as they reveal, and so I prefer to make a report of each case, very brief but accurate, so that the reader may come to his own conclusions. An attempt has been made to follow the course of all cases, and when not otherwise stated this has been done up to May 1, 1909, two years and nine months after my first injection. For obvious reasons the first twenty-three cases, already reported elsewhere, are included here.

Perhaps it may not be amiss to add that the cases were all unmistakable ones of tic douloureux; that some of them were frightfully severe; that most of the patients were quite disabled by the disease; that all had tried other forms of treatment; that a considerable number had undergone cutting operations; that some were very old and feeble, and that in no instance have I declined to administer the treatment on account of the severity of the case or of organic complications.

Case 1.—Aug. 2, 1906. Woman, aged 43; neuralgia of eight or nine years' standing. One injection each for middle and inferior branches. No return in two years and nine months.

Case 2.—Sept. 21, 1906. Woman, aged 49; neuralgia for sixteen years, middle and inferior branches; bad case. Five injections; complete relief for four months; slight return in lower branch; three injections; relief. Five months later a few slight pains in middle branch; 2 injections; immediate relief. Seven months after this or a year after the recurrence in the lower branch, this division again showed signs of returning pain. Two injections were made and, although apparently both missed, there has been no further pain in this branch. The last week in June, 1908, a year after the last injections for the middle branch, the patient had a few slight pains in this branch and June 30 received an injection. She has had no more pain; that is, with reinjections, relief for two years and seven months.

---

Case 3.—Dec. 17, 1906. Man, aged 51; neuralgia nine years, two branches; six injections; complete relief. Several months later he was still free from pain. No recent report obtainable.

Case 4.—Oct. 10, 1906. Man, aged 62; neuralgia for over three years, middle and inferior branches; had been operated on twice; had double antrum and frontal sinus disease. Six injections, complete relief; no recurrence in two years, six and a half months.

Case 5.—Jan. 1, 1907. Woman, aged 62; neuralgia for four years. Five injections for two branches, no pain after first injection. Of late some return of pain. Patient very nervous and has numerous complaints. Difficult to say whether or no there is return of the neuralgia, but I think there is, as sometimes eating and talking cause pain. Still, she is practically well so far as the neuralgia is concerned, two years and four months after treatment.

Case 6.—Jan. 19, 1907. Woman, aged 44; neuralgia about six and a half years. Had had two operations. Eight injections for two branches. Complete relief until June 1, then two slight pains; one injection for lower branch; no more pain until Oct. 17, 1908; then again two slight pains in same area. A single injection; no more pain. With reinjections, relief for two years, three and a half months.

Case 7.—Mar. 13, 1907. Woman, aged 50; neuralgia two years, two branches; bad case; three injections; instant relief. Patient remained well for eight months; then she developed an alveolar abscess in the area of the previous pain. After the tooth was extracted the pain continued and three injections failed to do more than mitigate her suffering. An *x*-ray picture then showed that the root cavity communicated with the dental canal; that is, the inflammation involved the nerve. Treatment of the cavity was undertaken by Dr. Gilmer and the pain subsided. In May, 1908, pain began again, apparently starting from a filled molar. The tooth was extracted with relief for some days. Then pain returned, when treating the alveolar cavity again gave relief. Through the summer patient was almost free from pain, but about November 1 it returned and she received three injections, none causing sufficient analgesia to be satisfactory to me. No pain until about March 1, 1909. Injections March 15 and 17, no more pain. With reinjections, relief (not quite complete) for two years, one and a half months.

Case 8.—Mar. 15, 1907. Woman, aged 23. Injections four times for inferior branch, without reaching the nerve. No relief. Patient left and later was operated on by Dr. Harris.

Case 9.—Mar. 19, 1907. Man, aged 60; neuralgia for five years. Five deep and one peripheral injection. Complete relief. Seven months later patient still free from pain. Unable to get more recent report.

Case 10.—April 19, 1907. Woman, aged 75, very feeble, bedfast, neuralgia thirteen years. Seen but once. Single injection; relief at once. There have been two recurrences. Each time patient's own physician has repeated the injections with prompt relief and she is now well, with "no indication of return." With reinjections relief for over two years.

Case 11.—April 23, 1907. Woman, aged 38; neuralgia ten months. Seen but once; single injection; immediate relief. Six months later patient had an occasional slight dart of pain. No recent report.

Case 12.—April 28, 1907. Woman, aged 54; neuralgia two years. Two injections. She has had an occasional slight twitch of pain but considers herself too well for further treatment, two years since injections.

Case 13.—May 5, 1907. Woman, aged 69; neuralgia for one year, first in middle, then in lower branch. One injection stopped the pain and patient declined further treatment until its return a year later, when her own physician repeated the injections (three), since which time she has had no recurrence. Period of relief with reinjections, two years.

Case 14.—May 16, 1907. Man, aged 60; confirmed neuropath; neuralgia for fifteen years; three branches; patient had had three operations. Received a deep and a superficial injection with notable relief. His physician continued the injections and he was completely relieved for a time and practically relieved until Dec. 27, 1908 (one year and seven months), when pains began to be severe. Feb. 3, 1909, I gave him an injection; three days later his physician repeated it and he is again free from pain (May 19, 1909).

Case 15.—May 17, 1907. Man, aged 62; neuralgia for five years, a very severe case. Received three injections for inferior and one for middle branch. Suffering relieved but still occasional twinges. Patient was compelled to leave city; Dec. 9, 1907, returned, having had some pain for three months, but not nearly so severe as before treatment; was given two injections with immediate relief. Two months later pain recurred. Patient given six injections. Relief was complete, but by October there were signs of recurrence and he received two injections. No more pain. Period of relief with reinjections, one year, eleven and a half months.

Case 16.—May 30, 1907. Man, aged 42; neuralgia for three months. Pain limited to supraorbital area but started by touches, etc., in area of infraorbital distribution. Patient received a deep orbital injection with some relief. Not caring to repeat this deep injection, I gave him a peripheral injection for the supraorbital and four or five deep injections for the middle branch. The latter was hard to reach, but finally he was completely relieved and has remained well. Just lately he has had an occasional slight sensation which seems to presage a return of the trouble.

Case 17.—June 12, 1907. Woman, aged 82. Neuralgia began in right inferior branch nineteen months before above date; for last year had also involved middle branch. As patient was feeble the depressing effect of the pain and the inability to eat had exhausted her to a marked degree. She received one injection for the inferior and one for the middle branch, which at once relieved her. I advised further injections but she declined and with the exception of a few slight twinges at rare intervals she has remained well, one year and eleven months.

Case 18.—June 25, 1907. Woman, aged 46. Neuralgia began ten years before above date in middle branch, radiating into supraorbital. Operation five years ago with no relief. I made two injections but failed to reach the nerve and the patient passed from observation.

Case 19.—July 1, 1907. Woman, aged 68; neuralgia of left lower branch for three years. I made two injections but missed the nerve both times and she returned to her home with practically no benefit.

Case 20.—July 3, 1907. Woman, aged 46; neuralgia for five years, principally in left lower branch. In this case I also failed to strike the nerve in two trials and the patient left.

Case 21.—Sept. 11, 1907. Woman, aged 54; neuralgia in right lower branch began ten years before above date but until the last five weeks had not been very severe. An injection was given with immediate though only partial relief, and as I could not guarantee a cure with one more injection the patient decided to take no more.

Case 22.—Sept. 13, 1907. Man, aged 77; advanced atheroma, senile heart; word-blind since an attack, evidently cerebral thrombosis, four months before above date. Neuralgia of left lower branch began twenty years before and had remained confined to this branch; from the beginning very severe. As talking immediately started the pain he was obliged to give up his profession (that of clergyman) and had been an invalid for the last twenty years. On account of the frightful pain caused by eating he often became weak and emaciated for want of nourishment. For several months he waited for a sufficient lull in his suffering to enable him to make the trip to Chicago. He was given three treatments and has not had a single pain since the first injection, one year and seven and a half months ago. In spite of his age and cardiovascular condition he has gained in strength and weight, and enjoys life.

Case 23.—Sept 28, 1907. Woman, aged 65; supraorbital neuralgia began two years before above date. At times very severe. After a peripheral injection of the supraorbital nerve it was found that pain could be started by touches or rubbing the skin in the infraorbital area, so patient was given one deep and one peripheral injection for the middle branch. This stopped all pain and she has had none since, one year and seven months.

Case 24.—Oct. 23, 1907. Man, aged 66. Pain began about twelve years ago in right middle branch, for the last six months shooting into supraorbital region. Patient took about one-half grain of morphin daily. I gave him an injection for the middle branch with instant relief. He slept all night without morphin and ate breakfast the next morning without pain for the first time in two years. I repeated the deep injection and also gave him a peripheral one for the supraorbital. I advised further treatment, as the analgesia was not marked, but he left for home. In about two weeks the pain returned and he suffered for a month. After that he was more comfortable for some time but is now having pain again and is taking morphin.

Case 25.—Oct. 30, 1907. Man, aged 73; neuralgia began fifteen years before above date in right upper lip but for a long time the lower branch had been involved as well. A bad case. I found the nerves very hard to reach. Patient received five injections for the middle branch and four for the lower, most of them misses. When he left for home he was having practically no spontaneous pain, although it could still be started by vigorously rubbing the face; but he said that he had not rubbed his face like that for ten years. Five months later he reported that he had had no pain in the middle branch area but was having considerable in the lower jaw, though not nearly so severe as before treatment. May 1, 1909, he reports that he has been suffering severely for a month.

Case 26.—Nov. 4, 1907. Woman, aged 62; began to have neuralgia eleven years before above date. Pain in middle and lower branches; numerous remissions. She received three injections for the middle and one for the lower branch with immediate relief and has had practically no pain since; that is, in eighteen months.

Case 27.—Nov. 6, 1907. Woman, aged 56; neuralgia for last six years and no free intervals. Infraorbital and inferior maxillary branches involved. Two injections for middle and one for inferior branch. None of these injections was entirely satisfactory from my point of view, but the pain was stopped, the patient felt "fine and dandy" and insisted on returning to her home. She gained six pounds in the next two weeks. Jan. 28, 1908, she returned, having had some pain for several weeks, though not nearly so severe as before the treatment. I gave her two injections for lower and three for middle branch with complete relief for seven months. She has had no further treatment. One of the injections for the middle branch caused a slight vertical diplopia which disappeared in two or three hours.

Case 28.—Nov. 12, 1907. Woman, aged 66; nervous, poor general health. Neuralgia of twelve years' standing, with intermissions, of left middle branch. Four years ago antrum opened, no relief. Patient received a single injection with immediate relief and has had no pain since.

Case 29.—Dec. 5, 1907. Woman, aged 58; neuralgia began three, possibly five, years before above date, right middle branch. Patient has arteriosclerosis, mitral regurgitation, cardiac hypertrophy and albumen in the urine. She received four injections, none of which was entirely satisfactory to me, but there was no return of pain for more than a year (Jan. 5, 1909). Her physician then gave her two injections. The second one relieved the facial neuralgia but the patient developed pain "all over the body" and her general health has failed. More definite details not obtainable.

Case 30.—Dec. 27, 1907. Man, aged 72. Pain began five and a half years before above date in left lower branch. About three weeks before coming to me his physician had given him three deep alcoholic injections with no benefit. I gave him three injections (the first of which missed) with complete relief. He remained free from pain until about July 1, 1908 (six months), when it began to return, and in November, 1908, his physician gave him two injections with considerable but not complete relief. In April, 1909, his physician again injected with some benefit.

Case 31.—Dec. 28, 1907. Woman, aged 62. This proved to be my most disastrous case up to this time. Pain began in right middle branch in the spring of 1905. For a year it was not very bad, then gradually grew worse, and for the last two or three months had been very severe. Six or eight weeks before date of treatment pus was discovered in the antrum but treatment of this by an expert afforded no relief. I injected the middle branch, but very imperfectly, and caused not only a deep hematoma but also a marked paresis of the external rectus, causing diplopia. Three days later the sixth nerve palsy was better, I repeated the injection and again failed properly to reach the nerve. Three days after this, under gas anesthesia, I did a third injection, this time with more success, as the analgesia was marked, and there has been no neuralgia since. But this injection rather increased the palsy of the sixth nerve so that the eye could not be turned outward beyond the middle line. The analgesia, too, involved the eyeball and caused a peculiar and uncomfortable feeling. The diplopia disappeared in about two months and in about two months more a careful examination by Dr. Burch of St. Paul, to whom I am indebted for the subsequent history, showed no trace of heterophoria. But, probably owing to anesthesia of the cornea, there remained a persistent tendency to irritation of the eye and to keratitis, requiring careful attention. In June, 1908, Dr. Burch informed me that the eye was doing well. Later in the summer the patient developed a corneal ulcer which healed but left an opacity. "Sensation in the cornea is still much diminished and there is some interference with normal lachrymation in this eye, with a catarrhal conjunctivitis which she keeps clean. There is no return of the tic douloureux." (Dr. Burch, May 16, 1909).

Case 32.—Dec. 30, 1907. Man, aged 52; neuralgia of two years' standing, mostly in left lower branch, though middle one is involved. Patient received two injections for the former with complete relief. I meant to treat the middle branch as well, but the patient suddenly left the city. For ten and a half months he was entirely free from pain. On Jan. 12, 1909, I injected the left lower branch with partial success. Immediately after this treatment the patient disappeared (I believe an alcoholic flight) only to return on January 24 for further treatment. Owing to his inebriated condition this injection was difficult and unsatisfactory. I declined to treat him further until he sobered up and he left.

Case 33.—Jan. 13, 1908. Man, aged 59. Neuralgia of left middle branch of ten years' standing and severe. Injected middle branch with immediate relief but the analgesia was slight and transient so I repeated the injection the next day but again failed to reach the nerve properly. The patient had to leave town. He was free from pain about six weeks; then it began to return. Over a year later, having received no treatment, he was suffering less than before the injections.

Case 34.—Jan. 18, 1908. Woman, aged 69. Severe neuralgia right inferior branch of about eight years' standing. Between May, 1905, and Nov. 28, 1907, five peripheral operations had been performed. The last time the operator had gouged open nearly the entire dental canal and scraped it. This gave no relief; rather made patient worse. I made an injection but the patient would not or could not hold still and I missed the nerve. Three and six days later I repeated the operation under gas with good results and she has had no pain since, one year and three months.

Case 35.—Jan. 22, 1908. Man, aged 74; chronic nephritis, arteriosclerosis, enlarged heart. Typical neuralgia, lower branch, of ten months' standing. Two injections. No pain whatever until the following October, nine months, when there appeared some slight pains in the middle branch which had not been injected. These pains never became troublesome and the patient died, March 14, 1909, of uremia.

Case 36.—Jan. 30, 1908. Man, aged 53. Pain began ten years before date of treatment in the right middle branch. Eight years before above date he had a very thorough peripheral operation which relieved him for four years. Then the nerve was cut off at its emergence from the skull at the foramen rotundum. This again gave relief for four years. Pain returned about eight weeks before I treated the patient and was as severe as ever. I was not at all sanguine as to results in this case because the nerve had been cut just where I would want to inject it and there must have been cicatricial tissue at this point. Furthermore, the zygoma had been cut across and its relations were changed. In addition, the patient had a large head and a very large, fat face (interzygomatic measurement quite six inches). I was fortunate, however, in reaching the nerve the first time and patient had instant relief. I repeated the injection five days later and he has remained entirely free from pain, one year and three months.

CASE 37.—Feb. 18, 1908. Man, aged 34. Apparently his neuralgia began when he was 7 years old. For the first four years it troubled him for only one or two weeks each year and was confined to the right lower branch. Gradually the trouble became worse and finally invaded the middle branch. From March, 1898, to some time in 1905 he was operated on eleven times, but two of these operations were for a salivary fistula caused by previous operation. A marked facial paralysis was the result of one or more of the operations. At one time the patient took as high as 15 grains of morphin daily. When he came to me he said he was taking only about ¾ to 1 grain daily. From February 18 to April 1 he received three injections each for middle and inferior branches. The first injection for the middle branch failed, but after the second he had no pain and there was no return until April, 1909. The patient said that he had "just lived in Paradise this last year"—the first year he could remember during which he had been free from pain. Injections were made April 27 and May 11, 1909, since which there has been no pain, but the analgesia is not sufficiently marked.

CASE 38.—Feb. 26, 1908. Man, aged 60. Neuralgia, right lower branch, of nearly three years' standing. In August, 1907, lower jaw was trephined and nerve resected, which relieved patient for five months. An injection at once relieved him except for an occasional "prick." Two more treatments were given and several months later he was said to have no return of pain. No recent report.

CASE 39.—March 3, 1908. Woman, aged 73. Pain began thirteen years before above date in right lower branch; eight years before same date extended to middle branch and now involved all three branches. I injected the middle branch with instant relief but evidently did not get the nerve well, as the pain returned the next day. No further injections have been made.

CASE 40.—March 18, 1908. Man, aged 51. A very severe case of ten years' standing. About four months after the onset the antrum was operated on and the infraorbital nerve is said to have been pulled out. Six weeks' relief. In July, 1907, peripheral operations were done on middle and inferior branches by a distinguished surgeon, which afforded considerable relief, but for two months only. The pains were so easily started and so severe that patient could not endure the lightest palpation of the bony landmarks, and washing the face was not to be thought of. Even the ordinary involuntary winking started the pains. He was given gas and the middle branch injected. Immediately after the injection the middle branch area could be rubbed without pain and patient drank a glass of ice water in comfort, feelingly remarking that that was the first glass or cup that had touched his lips for months. He received another deep injection for this branch and three peripheral injections for the supraorbital. Relief was complete until Jan. 25, 1909 (ten months), when slight pains began. Injections were made February 2 and 5 and the patient has remained well.

CASE 41.—March 24, 1908. Man, aged 70. Typical neuralgia began in right middle branch twenty years before above date. At times lower branch had been involved. In this case I had trouble in reaching the nerve. After the first injection he was notably better, but after three treatments in five days he was not entirely free from pain and the analgesia was very slight. As the patient was compelled to return to his distant home I gave him two peripheral injections which entirely relieved him. A year later he was having some pain and had had for some time but not nearly so severe as before treatment.

CASE 42.—March 25, 1908. Man, aged 45; neuralgia began three years before above date. Pain probably limited to lower branch but can be started from middle area. Not a very bad case and patient was given the castor-oil treatment with no effect. On April 6 the middle branch was injected and on April 8 and 11 the inferior one. He was at once relieved and remained well until early in March, 1909 (eleven months), when he began to feel slight "jerks" of pain. Injection given March 10 and patient has been well since.

CASE 43.—April 18, 1908. Woman, aged 41; neuralgia in left middle branch began two years before the date of treatment, extending to supraorbital three months before this date. This patient received five deep injections for the middle branch and a peripheral injection of superior branch with complete relief, but analgesia in the middle area was not complete and four months later pain began to return. At present (May 8, 1909) patient is having pain in middle and inferior areas, though not so severe as before the treatment.

CASE 44.—April 30, 1908. Woman, aged 59; neuralgia for eight years, involving middle and supraorbital branches. She received a deep injection of infraorbital and peripheral of supraorbital which at once stopped all pain. Contrary to my wishes, she returned to her home, but has had no recurrence as yet, one year.

CASE 45.—April 28, 1908. Man, aged 54. Six years before above date pain began in right lower branch and soon spread to middle as well. Within two weeks patient received four injections for the inferior branch and, although the analgesia was unsatisfactory, he was relieved and has remained well except for occasional slight "reminders," one year.

CASE 46.—May 9, 1908. Colored man, aged 48. Five years before above date neuralgia began in right infraorbital area. Three years later antrum opened, no result. The middle branch was injected with instant, almost complete relief, but patient received three more injections with complete relief. After the second and fourth injections there was paresis of the abducens which disappeared in a few days. Four months later pain began to return; two injections, relief for six months; then patient was given four injections, which again relieved him. This was a difficult case. The *x*-ray picture (page 1986) shows needle in position for injecting middle branch.

CASE 47.—May 14, 1908. Woman, aged 53. A severe case of ten years' standing, middle and superior branches involved. For the last five months there had not been an hour's respite, day or night. Deep injection of middle branch and peripheral of upper branch at one sitting. The pain ceased at once but in the next two weeks patient was given two additional injections for the middle branch. About the end of August she began to be annoyed by pruritus in the supraorbital area and on September 26 I injected this nerve, hoping to stop the itching. There was not instant relief but gradual improvement. Apparently this injection caused alopecia in a small wedge-shaped area at the hair margin, but the hair soon grew again. About November 1 patient began to have pain, this time apparently starting from lower branch, which never had been treated. It was not bad and nothing was done until Jan. 24, 1909, when I injected inferior and middle branches with instant relief and the patient has remained practically well, though she has some discomfort of some sort. From her letter it is impossible to say whether she has any neuralgia or not.

CASE 48.—May 17, 1908. Man, aged 36; neuralgia, middle branch, began four years before date of treatment; during last three years also occasionally in inferior branch and for last eighteen months pain sometimes started by touches, etc., in area of supraorbital. The middle branch in this case was very hard to reach. Patient received five injections at intervals of three to five days, and while there was some relief from the earlier ones the last injection was the only one which got the nerve properly. He received one peripheral injection for the supraorbital. The second deep one caused a very slight paresis of the sixth nerve which disappeared in a day or two. He has remained well.

CASE 49.—June 2, 1908. Woman, aged 57; neuralgia for last ten years, middle and inferior branches, sometimes radiating into supraorbital. She received three injections, one for the middle (not a very good one), two for the inferior branch. After the first injection she slept all night; the first time in many years. Relief was complete until late in December, when pain returned in lower branch. Injections of this branch made Jan. 7 and 10, 1909, relieved her and she has remained well.

CASE 50.—June 3, 1908. Man, aged 76; physically senile, enlarged prostate, marked atheroma and a bad heart. Neuralgia of right middle branch for last fifteen years. Injected June 4 and 6. Although the pain ceased entirely the analgesia was not sufficient to satisfy me. Contrary to my wish the patient returned to his home. Within two weeks he was again having some pain. On June 26 I again injected and caused a free deep hemorrhage. Swelling below and above the zygoma was marked and patient complained of headache, evidently caused by the pressure. This pain over right side of head lasted about thirty-six hours and the patient felt weak and "knocked out." The pulse was irregular and none too strong and it was five days before patient felt able to make the trip to his home, some six hours distant. He has had no return of pain and "has good health for one of his advanced years." But apparently the pressure of the hematoma was too much for his diseased vessels and poor heart, as the injection was followed by some necrosis of the hard and soft palate and I infer from his physician's letter that a molar tooth was also lost. These lesions healed, leaving no bad effects except slight stiffness of the jaw joint.

CASE 51.—June 4, 1908. A very nervous and delicate woman of 73; apparently had something like neuralgia fifty, forty and thirty years ago; each time for several weeks. Present trouble began three or four years before above date; now limited to right lower branch. Injections June 5 and 7 with some relief, but far from complete. Patient decided to return to her home. Aug. 6, 1908, her physician reported: "Her face is much better, she is fleshier and her general appearance is 50 per cent. improved." She remained "very much better," though not entirely free from pain, until about April 1, 1909, when she again began to suffer severely.

CASE 52.—June 14, 1908. Man, aged 75; neuralgia for twenty-five years; for the last ten years very severe and for the last five years nearly continuous. Middle and inferior branches involved, with pain radiating into superior. This proved a hard case to treat. Patient received four injections for the middle branch and four for the inferior, besides one peripheral injection of the middle one, but finally was entirely relieved and has remained well.

CASE 53.—June 22, 1908. Man, aged 77; atheromatous arteries; neuralgia of right middle branch off and on for last two years; occasionally radiated to upper or lower branch. As this was not a severe case and patient when seen was not suffering I made two peripheral injections on succcessive days and advised him to wait. He was entirely relieved and remained free from pain until his death five months later, probably from angina pectoris.

CASE 54.—June 26. 1908. Woman, aged 60; neuralgia of lower branch last eight months. I saw this patient in transit and made one injection which did not get the nerve well and from which she received no benefit. On the contrary, she writes me that for three weeks afterward the pain was worse than ever. Subsequently she improved, evidently a period of spontaneous amelioration and not due to the injection.

CASE 55.—June 26, 1908. Physician, aged 49. His neuralgia began in October, 1904. In April, 1906, an eminent surgeon did the Abbé operation, which relieved him entirely for nearly a year and practically for nearly fourteen months. When seen the pain was as bad as ever and, as before, limited to inferior branch. This branch was injected June 26 and 30, with instant and complete relief, but six months later pain began to return and invaded middle area. In January, 1909, he received three injections for lower and one for middle branch. I thought latter should be treated again but patient was entirely free from pain, went home, and has remained well.

CASE 56.—June 28, 1908. Woman, aged 72, with enlarged heart and irregular pulse. Forty-three years ago the lower jaw was injured in the extraction of a tooth. This was followed by severe paroxysmal pain. Soon after, a surgeon in attempting to remove dead bone and cut the nerve, fractured the jaw. After this there was no pain for a year, when it returned. Since then the patient has undergone eighteen peripheral operations, each one relieving her for a longer or shorter period. Paroxysms exceedingly severe. Injection made at once. Relief was immediate but not complete, as she had an occasional pain during the next few days. Four days later treatment was repeated, after which she had only an occasional pain, never severe. Evidently she needed further treatment but was satisfid with the result and prepared to wait. The slight pains disappeared and there was no sign of neuralgia for six months. On Feb. 15, 1909, she received an injection and has been perfectly free from pain since.

CASE 57.—June 27, 1908. Physician, aged 40; neuralgia of right middle branch began over five years before above date. In spring of 1905 it extended to superior branch. In 1906 antrum opened and in August, 1907, infraorbital nerve resected, which gave him not complete but practically complete relief until a few days ago, ten months. Paroxysms now frequent and rather severe. Middle branch was injected June 27 and July 1, and peripheral injection of supraorbital made June 28. Relief was complete and patient has had no pain, although through the winter he was much exposed to wind and weather.

CASE 58.—July 1, 1908. Man, aged 42; neuralgia began twenty years before above date in supraorbital division; a year later changed to infraorbital division and two or three years before above date again began to invade supraorbital. Injection of infraorbital July 1 and on same day peripheral injection of supraorbital. Pain was relieved but the deep injection caused transient paresis of abducens. Patient has remained well.

CASE 59.—Sept. 10, 1908. Man, aged 45; tuberculous hip with sinus since age of 8. Rectal fistula for five years, neuralgia right middle branch for last six years, of inferior branch last seven months, and for two or three months radiating into supraorbital. Numerous paroxysms every day. Patient received five injections for the middle and three for the lower branch; complete relief and no recurrence.

CASE 60.—Sept. 18, 1908. Woman, aged 66; neuralgia of left middle branch for ten years; for last six months so severe that patient's strength had suffered from lack of food. She received eight injections in all, though there was practically no pain after the third one. There was great difficulty in reaching the nerve. April 22, 1909, considerable pain. Patient now better but doubtless will need treatment before long.

CASE 61.—Sept. 25, 1908. Small, delicate, nervous woman, aged 58; neuralgia for four years. In January, 1908, a deep injection was given by another physician with immediate relief. After two weeks there was a little pain and in February injection was repeated with relief for five months. In August she had received three injections with no benefit. I gave her three injections, the first two missing, the third getting the nerve well, since which time she has been entirely well as far as the neuralgia is concerned.

CASE 62.—Oct. 3, 1908. Woman, aged 37; neuralgia of superior maxillary division for six years. Resection of nerve July, 1905, relief for fifteen months. May, 1907, nerve was again resected, the foramen injected with osmic acid and then plugged with a silver screw. Relief for nine or ten months. Supraorbital nerve said to have been divided three weeks before my treatment, but there was no analgesia. I made deep injection of middle branch and peripheral of upper; immediate relief. Patient left the city the same day. Five months later slight return of pain, but patient is still relatively comfortable.

CASE 63.—Oct. 10, 1908. Man, aged 64; neuralgia for ten years; for first five in right lower branch only, for last five in middle as well. In the last four years not a single day free from pain; generally about 150 paroxysms daily. Three injections; complete relief, no recurrence.

CASE 64.—Oct. 17, 1908. Woman, aged 60; neuralgia of right middle branch began three and a half years before above date. Three months before my treatment another physician gave patient several peripheral injections of alcohol with great relief. I made one deep injection with but slight effect and the patient decided to try Eddyism.

CASE 65.—Oct. 30, 1908. Man, aged 58; neuralgia for three years, lower and middle branches, radiating into upper; a bad case. Four months before date of my treatment a well-known surgeon injected osmic acid without result. This patient received two injections for the inferior and five for the middle branch. The latter was exceedingly difficult to get. I tried going in in front of the coronoid process, behind it (below the zygoma) and above the zygoma. The patient was completely relieved, but about the middle of February, 1909, began to feel signs of recurrence. Between February 22 and March 5 he received two injections for inferior maxillary and two for superior. As I could not reach the latter, owing, I think, to the bony conformation, I injected the alcohol at the infraorbital foramen. Patient was relieved and there has been no recurrence.

CASE 66.—Oct. 31, 1908. Woman, aged 63; neuralgia of right lower branch began six years before above date. Two years later evulsion of nerve; relief for a year or more. For last six months pain worse than ever before. Three months before I treated patient a surgeon again operated and gave four injections of alcohol. No relief from operation; some from the injections. I gave her two injections, the first missing. Complete relief and no recurrence.

Case 67.—Dec. 11, 1908. Woman, aged 60; neuralgia for five years, first and second branches involved. Arteriosclerosis and hypertrophy of heart. She received three deep injections for middle branch and one peripheral one for the superior branch. Complete relief. Recently slight signs of return.

Case 68.—Dec. 15, 1908. Man, aged 48; neuralgia began eighteen months before above date in right upper jaw. For last three months lower also affected. Poor general health, dilated heart, and in last three months four attacks of unconsciousness. He received one injection for middle branch and three for the lower. Entire relief and no recurrence. Patient has had no more fits.

Case 69.—Dec. 23, 1908. Man, aged 65; senile; arteriosclerosis, intermittent heart, feet cyanotic. Neuralgia of middle and inferior branches for about one year. Patient received four injections for inferior branch, one deep and one peripheral for the middle branch. He was relieved of pain but this is the most unfortunate case I have had. Immediately following the deep injection of the middle branch the patient showed paresis of the abducens and some analgesia of the supraorbital area and the next day a keratitis which finally eventuated in a superficial ulcer. He had the care of a skilled oculist but left the city and I have been unable to get a later report.

Case 70.—Dec. 29, 1908. Man, aged 74; atheromatous arteries, mitral and aortic murmurs. Severe neuralgia of left lower branch for one year. The first injection missed the nerve. The next day patient had what apparently was a slight cerebral thrombosis and operations were deferred until Jan. 11, 1909. An injection on this date missed, but two days later I struck the nerve at a depth of 5.5 cm., since which time the patient has been entirely free from pain.

Case 71.—Jan. 6, 1909. Man, aged 61; neuralgia for fifteen years, all branches involved. Mitral disease, albumin and casts in urine. Excision of nerves performed seven years ago; partial relief for a year. Patient received three deep injections for middle branch, one for lower and a peripheral injection for supraorbital. Complete relief and no recurrence.

Case 72.—Jan. 14, 1909. Man, aged 47; very nervous; enteroptosis; general health poor. Neuralgia for nearly two years, middle and inferior branches. Three injections, not entirely satisfactory as regards analgesia but relief complete. Patient went home and has had no return of pain.

Case 73.—Jan. 23, 1909. Woman, aged 45; neuralgia began twelve years ago and from beginning involved all branches. This patient had a remarkably large face for a woman, with prominent cheek bones and most unusual thickness of the lower jaw. Apparently the deeper bones were also thick, for I had great difficulty in reaching the nerves. Patient received three deep injections each for middle and inferior branches and one peripheral injection for the first division. Complete relief and no return of pain.

Case 74.—Mar. 9, 1909. Man, aged 46; neuralgia for fifteen years. Pain in middle branch but started by touches in supraorbital and inferior maxillary areas. Four years before above date resection of superior maxillary; relief for one year. Six months before same date four deep injections of alcohol; relief for three months. Three more injections; no relief. I gave patient three injections for lower branch, one deep and one peripheral for middle branch, and he has had no more pain on that side. About Mar. 18, 1909, he began to have typical neuralgia pains in *left* lower area and April 5 and 8 I injected this branch, since which time patient has been well.

Case 75.—Mar. 12, 1909. Man, aged 62; arteriosclerosis, hypertrophied heart. Neuralgia began ten or twelve years ago in right middle branch; a year later extended to supraorbital. Many remissions, once for a year. Now very severe. Four or five years ago wedge-shaped piece excised from upper lip; no relief. I gave patient a deep injection of superior maxillary and peripheral one of supraorbital. Instant relief, no return of pain.

I think that there can be no doubt whatsoever that when the injection reaches the nerve the pain is stopped at once. In this sense I have had not a single failure. The greatest drawback to the method is the uncertainty of reaching the nerve on any given trial. But if the patient is willing to persevere he is practically certain of relief. Of course, in many cases one succeeds the first time.

The danger of the operation is as nearly *nil* as can well be. I know of no fatality and think none has ever been recorded. Nor have I heard of a single case of infection. I have had none in over 300 injections. Disagreeable complications are exceedingly infrequent, my worst, indeed practically all, having been in Cases 31, 50 and 69. In a few cases injection of the middle branch has caused a small hematoma which did no harm and occasionally I have produced transient paresis of the sixth nerve. In this connection it is worthy of note that in the 75 consecutive cases covered by this report 36 patients were between 60 and 70 years old, 13 between 70 and 80 and one over 80.

The procedure is not excessively painful; at least patients do not often complain of it. An anesthetic is very rarely necessary. In four cases I have given gas, but in only one of these (Case 40) was it absolutely required. There is no shock. Most of my injections have been done in the office, and in a few minutes the patients are ready to walk out, though I prefer to have them lie down for twenty or thirty minutes. Queer as it may seem, the alcohol itself causes no pain after a few seconds.

There is no reason to believe that these injections effect a radical cure, though I suppose that occasionally this might be the result. The period of relief to be attained is hard to estimate. A good injection, as shown by marked analgesia, may be expected to relieve for from one to three years, possibly more. One trouble I have had is to get patients to have more treatments after the pain has been stopped. The sufferer is satisfied as soon as relieved.

Reinjections after recurrence and injection in cases in which patients have already undergone peripheral operations seem to be just as successful as primary injections. I have never had occasion to give an injection to a patient who had been subjected to the ganglion operation.

While I do not at all wish to be understood as making a special plea for this treatment, recognizing, as I do, its many weak points, it is only fair to the reader that I should state my opinion that in the majority of cases it is the simplest, least hazardous and best. Should it finally fail, the Abbé or the Gasserian operation is still open to the patient. It will occur to every one that by this means old, feeble and infirm sufferers may be made comfortable at minimum risk until length of years or intercurrent disease leads to the final *exitus*.

34 Washington Street.

ABSTRACT OF DISCUSSION

Dr. D'Orsay Hecht, Chicago: The conclusions that I have come to concerning the deep alcohol injections are based on an experience with 38 cases to date, in which I may have totaled 150 injections. I can share Dr. Patrick's sense of disappointment in missing the nerve, and, on the other hand, have experienced the agreeable feeling of having produced immediate analgesia in the related area by getting the solution into the nerve, than which there can be no more pleasant sensation for patient and operator alike. My youngest patient was 25 and the oldest 90. In both I had good results. I had one experience in injecting the ophthalmic branch which leads me to the conviction that I shall not do it again. The amount of ecchymosis and edema of the conjunctiva and eye was such that I had to resort to cold applications and scarification. No permanent damage was done, but the condition caused me to feel uncomfortable for several days. In another patient, a bleeder, I was unfortunate enough to encounter hemorrhage, resulting in the formation of a rather large hematoma in the cheek, which was slowly resorbed. The patient was a woman from a neighboring state, who had typical trifacial pain. The diagnosis of the underlying pathology was very difficult. Sinus disease was known to have been present, brain tumor was suspected, and all this in a highly neurotic individual. After the first injection she had relief for about two months. She returned to her home and the recurrence of pain led to surgical intervention in the form of placing a screw in the infraorbital foramen. This was done without relief and the patient in three months returned for further injections, which were likewise without benefit to her.

I should like to call attention to a class of cases thought by some to be trifacial neuralgias, but which are merely minor facial neuralgias. They require to be differentiated, and unless they conform to the well-known clinical description of trifacial disease, I should say that they were unsuited for the alcoholic treatment. When these patients with vague continuous pain are subjected to *x*-ray examination, some underlying pathology referable to the teeth, jaws or sinuses is always revealed. I might add that a small, flexible film placed in the mouth along the borders of the teeth supposedly giving rise to the pain will disclose the dental condition better than an outside exposure. In every case of trifacial pain, whether typical or atypical, I seek to ascertain the underlying pathology with every adjunct to diagnosis at my disposal.

On the whole, my results have been good, although I reiterate what Dr. Patrick has said, that at times I have felt discouraged with the method. I shall, however, continue to do the trifacial injections with alcohol, feeling about them as I did two years ago, that they afford in a large proportion of the cases the best kind of palliation known to me and borne out by my experience of free intervals from pain from the shortest period of four weeks to the longest of two and a half years.

Dr. B. R. Tucker, Richmond, Va.: I recently reported in a local journal thirteen cases of trifacial neuralgia treated by medical means. After trying all medical treatment in one case and it having failed, the injections were tried and proved successful for three months. The patient, a woman of 72 years in very wretched health, came back and the operation was repeated and proved successful again.

Dr. C. L. Dana, New York: In the class of cases that Dr. Patrick refers to as trifacial neuralgia, does this term mean *tic douloureux?* This seems to me a specific kind of neuralgia occurring with peculiar symptoms almost always after the fortieth year in the degenerative period of life. The facial neuralgias which occur in early life are usually sympathetic, but these sometimes take on themselves the typical aspect of a *tic douloureux*. I should like to know whether his successes are not with older patients.

So far as my experience goes in the ordinary *tic douloureux* of the degenerative period of life, when the disease has not been very long standing, the operation seems to work satisfactorily. But in the very prolonged cases a sort of psychosis is added to the neurosis, and the operation does not seem to be of so much benefit.

Dr. Hugh T. Patrick, Chicago: As accurately as I could make the diagnosis these were all perfectly typical cases of *tic douloureux*. Most of these patients had passed the fortieth year. The age question is rather interesting; and those in the thirties (and there were very few of them) were not to be distinguished, by me, at least, from the perfectly typical cases in older persons; that is, the intermittent, short, violent, exceedingly severe pains with intervals of remission of various length. The pains would be started by a slight sensory stimulus on the face, such as washing it, touching it, eating, talking, etc. Really typical trifacial neuralgia is something apart and different from anything else and the diagnosis is not difficult. As regards the operation, I would say the older the people the easier the job; the tissues are soft, they are not fat, the distance to go is not so great. The tissues being soft, one can handle the needle better after it is in and can feel out the way more easily in the old people than in the younger, more vigorous and more muscular patients, in whom the fasciæ are tough and hard and in whom there is considerable muscular mass. Those are the cases which have been difficult as a rule; although occasionally in an old person I find bony trouble.

Another thing that I am generally asked is whether I give an anesthetic, and whether the injection itself is very painful. I do not give an anesthetic as a rule. In most of these cases the operation, if you may call it such, is done in the office, although I can not say that I advocate that particularly, only it has been convenient to do it so. In a few cases I have had gas given, once in the case of a woman who had a good many injections, the disease being of seventeen years' standing, always with success, and who at present is perfectly free from pain. She objected to the discomfort of the injection and had gas a number of times. One patient was such a bad case, also of long standing, that I could not even palpate the face, let alone scrub and clean it, without causing this terrible pain. When I put my finger on the malar bone to feel the process the man could not keep still—the exceedingly lancinating pains were too much for him. I gave him gas and then the injection and when he woke up he was free from pain. I rubbed his face with ice water and handed him a glass to drink; he was afraid to try it—he said he didn't want to—but he finally drank it and said: "That is the first vessel that has touched my lips for four months." His wife had fed him with extreme care from the other side of the mouth with a teaspoon so as not to touch the side of the face where the pain was.

One old woman who had had something like nine operations and was exceedingly nervous and hypersensitive could not or would not keep still and I missed the nerve entirely. She then went into a hospital and I gave her two injections under gas. That is about a year and eight months ago, and she has remained entirely free from pain since. The injections after other operations are interesting. I have given injections after all operations except the Gasserian operation. I never have had a case in which the Gasserian ganglion had been removed; but I have had one after an intracranial section of the nerves; also one case in which a screw had been inserted into the infraorbital foramen, and those injections were as successful as the others.

CERTAIN HITHERTO UNPUBLISHED DATA CONCERNING THE INSANE

R. M. PHELPS, A.M., M.D.
Assistant Superintendent Rochester State Hospital
ROCHESTER, MINN.

One of the most natural and most common of questions concerning the insane, as they are found massed in a hospital, is: "What becomes of them all?" Oddly enough, this question has never been fully answered. At first glance the question seems easy to answer, but a search among the common tables shows that it has not been found easy.

Seeing this, I was led last year to attempt a tabulation (Table 1) which should show what became of them, so far as hospital records answer that question. That is, of a given consecutive or average number of admissions of patients having the average of characteristics I would like to show how many die in the hospital, how many leave "recovered," how many leave "improved," how many leave as "unimproved," and how long it takes to secure each of these results. While this table is closely exact as to the shorter durations, it is yet, of course, and as a whole, a "close approximation," and is derived from a study of the cases in the Rochester State Hospital. It also disregards a study of what may become of patients after six months of probation and discharge.

Table 1 assumes 1,000 consecutive admissions of insane patients, and then, keeping to the same individual cases, and disregarding all subsequent admissions, follows these 1,000 persons till all are disposed of under one of four headings: (1) "died," (2) "discharged as recovered," (3) "discharged as improved," (4) "discharged as unimproved."

TABLE SHOWING TERMINATION OF CASES OF 1,000 NEWLY ADMITTED INSANE PERSONS

Years of Stay in Hospital.	Died.	Discharged, recovered.	Discharged, improved.	Discharged, unimproved.	Remaining.
During 1st year........	150	160	150	5	535
During 2d year..	50	27	69	5	384
During 3d year.........	40	5	25	4	310
During 4th year........	30	3	13	4	260
During 5th year........	20	2	5	3	230
During 6th year........	15	2	3	3	207
During 7th year........	15	1	2	2	187
During 8th year........	14	...	1	1	171
During 9th year........	13	...	1	1	156
During 10th year........	13	...	1	1	141
During 11th year........	13	...	...	1	127
During 12th year........	12	...	...	...	115
During 13th year........	11.	...	...	...	104
During 14th year........	11	...	...	...	93
During 15th year........	10	...	...	...	83
During 16th year..	10	...	...	...	73
During 17th year........	10	...	...	...	63
During 18th year........	9	...	...	...	54
During 19th year........	8	...	...	...	46
During 20th year..	7	...	...	...	39
During 21st year........	6	...	...	...	33
During 22d year.........	6	...	...	...	27
During 23d year.........	5	...	...	...	22
During 24th year..... .	5	...	...	...	17
During 25th year...... .	4	...	...	...	13
During 25th to 30th year..	8	...	...	...	5
During 30th to 35th year..	4	...	...	...	1
During 35th to 40th year..	1	...	...	...	...
Totals	500	200	270	30	

I think that most people, even those acquainted with the insane, will be surprised at some of the items. I will call attention to some of them.

1. Nearly one-half the cases (465 out of the 1,000) are terminated before they have been one year in the hospital.

2. About one-fifteenth of the patients (150 out of the 1,000) have died before one year of their residence is over. This is partly due to the admissions of "seniles" and "paretics," but partly to the little-noted indirectly fatal character of the acute stages of insanity.

3. A very large number of patients stay out in the world as "improved." I do not make allowance in this table for "relapses," but, as hardly ever more than one patient out of ten relapses, even if these be allowed for, yet rather more patients go out and stay out as "improved" than go out and stay out as "recovered."

4. It takes approximately forty years to terminate all the cases. The older patients live about as long as they would if not insane.

THE LIABILITY OF DIFFERING AGES TOWARD INSANITY

It is commonly said, and all hospitals have tables which show, that the most common age to become insane is about the ages 30 to 35. This is true as to the occurrence of the greater number of cases. It is instantly assumed, however, and is commonly stated that the greatest liability to become insane is at such ages. This is not true.

The reason that it is not true lies in the fact that the number of people living is less at each succeeding age. Indeed, the age of nearly one-half the population living is less than 20 years, and yet very few cases of insanity come from that period.

To illustrate this, suppose there are in a community 1,000 people of the age of 55 and 3,000 people of the age of 25. Now, if 10 people from the 1,000 of the age of 55 go insane, and if 30 people of the 3,000 of the age of 25 go insane, then there will be the same percentage liability at each age. Yet the actual numbers are as 3 to 1.

Clear as this seems, I find no table incorporating this fact or in any way recognizing it as a vital and important practical truth. Table 2, computed by comparing the total population of Minnesota with its total insane committed, is formed to show the actual liability per million, and also the actual percentage liability as between the different age decades.

COMPARATIVE LIABILITY TO INSANITY IN EACH DECADE

Age by decades.	No. living in each age in Minn. (census, 1900).	No. insane admitted in Minn. in 1901-1902.	No. insane of each age decade *admitted* in Minn. per million people living at that age in Minn.	Proportionate chance of becoming insane at each age decade, as compared with other decades, in percentages.
				Per cent.
Under age 20....	807,978	54	66.8	.410
From age 20-30..	309,281	380	1257.7	7.727
From age 30-40..	252,248	522	2069.3	12.710
From age 40-50..	172,688	379	2194.2	13.481
From age 50-60..	103,189	218	2112.6	12.980
From age 60-70..	63,388	122	1924.6	11.824
From age 70-80..	31,026	78	2514.0	15.447
Over 80	7,494	31	4136.6	25.415
Totals	1,747,292 (People in Minn.)	1,793	16275.8 (Sum of relative chances.)	99.994

Column 4 is obtained by multiplying Column 3 by 1,000,000 and dividing by Column 2. It is from the proportion: "807,978 is to 54, as 1,000,000 is to the required number."

Column 5 is obtained by dividing the chances per million of each decade by the total number of chances. It merely gives the chance of each decade as compared with the whole in terms of parts of 100. It is a relative percentage.

The caution must be added that this last column does not show the percentage of insane committed, but only the relative chances of becoming insane in one decade as compared to the other decades and as compared with one hundred chances. If there were an equal number of people at each age, this would be the proportion committed from each decade.

A Case of Displacement of the Descending Colon.—Mahmoud Hamdy and Mustafa Fahmy Sorour, of the school of medicine, Cairo, Egypt, state (*Jour. Anat. and Physiol.*, April, 1909, xliii, 242) that it is quite common to find considerable variations in the positions of the various parts of the colon in Egyptian cadavers. There have been reported from Egypt a case of intestinal obstruction, in which the pelvic colon, on post-mortem examination, was found to be 83 cm. in length (1 cm. less than the longest recorded example), a colon passing obliquely across the body postperitoneally, from the cecum to the splenic flexure and the case described below, in which the pelvic colon lay as an inverted distended U-shaped tube in front of and adjacent to the cecum, appendix and distal end of the ileum, in such a position as to give considerable confusion and embarrassment if it became necessary to perform colotomy or to examine the region of the appendix. "The whole oblique extent of the colon, from the splenic flexure to the pelvic colon, was placed behind the peritoneum, which covered only its anterior aspect. The whole of the left side of the abdomen below the level of the kidney was devoid of any colic contents. The root of the pelvic mesocolon was in contact with the cecum, and there was a very deep and narrow cleft between the two, occupied by the appendix and partly roofed over by a peritoneal fold passing from the pelvic mesocolon on to the anterior surface of the ileum and cecum."

THE PLAGUE ERADICATIVE MEASURES (SQUIRREL CAMPAIGN) IN CONTRA COSTA COUNTY, CALIFORNIA

W. C. RUCKER, M.D.
Passed Assistant Surgeon, U. S. Public Health and Marine-Hospital Service, Commanding Contra Costa Detachment
ALAMO, CAL.

> The hypothesis of an epidemic (or more properly an enzootic, as we are speaking of animals) has greater chances of being true. This enzootic is prevalent in a permanent manner in one species of animals which is found in the mountains of Asia. From this animal the virus is automatically propagated to the rat and from the rat to man. Plague seems thus to be an accidental disease in the rat as it is in man, and it is necessary to trace further back to discover the animal which acts as the host for the bacillus pestis. Beliatsky and Reschtnikoff first, and Zabolotny later have drawn our attention to a rodent of Mongolia which they believe to be this animal host. This rodent is a sort of marmot, the *Arctomys bobac* or *tarabagne* which presents from time to time lymphatic swellings. The natives hunt it for eating purposes and also on account of its fat. According to these three Russian authors the inhabitants of certain uncivilized districts of Siberia receive plague periodically from this animal. The intermediary to the rat might thus be exterminated. One understands the full importance of this discovery if it should be confirmed. To eradicate plague forever from the surface of the globe it would be sufficient to declare a war of extermination no longer against the rat, which is cosmopolitan, but against this rodent of Tibet from which the disease spreads to every part of the globe. *La Pathologie Exotique,* LeDantec.

For several years human deaths from plague have been a matter of annual occurrence in Contra Costa County, and it has been known that for at least the past four years some epizootic has been spreading among the ground-squirrels of that region. This animal, the *Citellus beechyi,* resembles the *Arctomys bobac* very closely in habits and appearance, and it is not at all improbable that it bears a similar relation to the perpetuation and distribution of bubonic plague to other species. Ranchers and others who have observed the squirrels closely state that in 1904-5-6 they died by the thousand. They would emerge from their holes and stagger about as though they were drunk, and on many occasions it was possible for one to kill them with a stick. Their fur was turned the wrong way and in some instances they were emaciated, and presented swellings beneath the jaws or in the axillæ. Numbers of them were seen crawling on the ground in a dazed condition, apparently having lost all sense of direction, blunderingly trying to find their holes. It is not at all improbable that some were suffering from the pneumonic form of the disease. Several very intelligent ranchers who took the trouble to open the bodies state that the lungs were dark red in color and resembled liver in consistency. In many places the squirrels died in such numbers that the buzzards came in great flocks, and the air was redolent with the odors of the decomposing bodies. Up to that time the squirrels had been a great pest, levying a heavy annual tribute on the products of the farmer. On some of the ranches they existed in such great numbers that "the entire hillsides seemed to move with them." In one part of the county the vineyards had to be surrounded with sheet-iron fences which extended two feet below the ground and three feet above, in order to prevent the squirrels from destroying both the grapes and the vines. Even yet there remain valleys where they are so plentiful that one may see hundreds of them in a few minutes' walk. They may be observed playing about or eating the grain and seeds on which they subsist, and usually there are one or two sitting bolt upright by the entrance to the burrow. On the approach of the hunter they will whistle, and after a short time it is very easy to recognize the meaning of these signals. If one sharp whistle is given the animal will usually sit still, and it is still possible to get a shot. If he gives one sharp whistle and goes down into the hole, it is safe to wait a few minutes for him, but if he gives one sharp whistle followed by two or three trills in a descending scale it is simply a waste of time to wait for him to come out, because he has been thoroughly frightened and may not reappear for two or three hours. In many cases entire crops were destroyed by the squirrels. As a result this epizootic was welcomed because the rancher realized that the extermination of these in such hordes meant a great saving to him.

The epizootic was assigned to various causes. Some thought that it was due to the blasting with dynamite in the construction of a tunnel through the Berkeley hills. Others maintained that it was due to some disease which had been inoculated in the squirrels by some of the professors at the State Agricultural College, while others affirmed that it was due to a product called "squirrelene," which came into general use about that time.

The epizootic seemed to begin in the northern part of the county along the coast of Suisun Bay, and rapidly spread as far east as the river and south into Alameda County. Some observers have stated that the disease entered the county from the south by way of the Niles Canyon, while others believe that the route of entry was through the Moragua Valley. If an entrance was gained through the first route, the hypothesis that the squirrels were infected by rats brought to this country on the sugar ships from Honolulu might be tenable. If the disease came into the county through the two last-mentioned routes, it would seem more likely that Oakland was the infecting nidus. This, however, is a departure into the realm of speculation, which is of little profit.

Surgeon Rupert Blue, of the U. S. Public Health and Marine-Hospital Service, and Dr. N. K. Foster, Secretary of the State Board of Health, looked into the matter, but it was impossible at the time to go into very extensive investigations. In all probability this disease was bubonic plague, but this could not be determined until the summer and autumn of 1908, when the investigations following two human cases resulted in the discovery of four plague-infected squirrels. The pathologic findings in these animals, which were the first cases of natural plague among ground-squirrels ever seen in America, is the subject of an exhaustive monograph by Acting Assistant-Surgeon William H. Wherry, U. S. Public Health and Marine-Hospital Service.[1] Three of these squirrels were shot and one was found dead. All were discovered within four miles of Bay Point, California. One of these was found on the ranch where a boy died from bubonic plague in the summer of 1908; the others were secured near the coast of Suisun Bay. These findings removed the question of squirrel plague from the field of theoretical consideration and placed it on the solid foundation of fact. It remained, however, to prove the extent of the infection and to evolve, if possible, a plan for the final eradication of the disease, which, having gained a permanent foothold in California, would continue as a perpetual menace to the bay cities, the state and the entire union.

In April, 1909, Surgeon Rupert Blue, acting under the authority of Surgeon-General Walter Wyman, of the U. S. Public Health and Marine-Hospital Service, began an active campaign in Contra Costa County, one of the central counties of the state. It is bounded entirely on the west, north and east by water, its western boundary being San Francisco Bay, its northern boundary the San Pablo and Suisun Bay, its eastern boundary the San

---

[1] Wherry, W. H.: Jour. Infect. Dis., v.

Joaquin River and its southern boundary Alameda County. It is also bounded, to a certain extent, on the west by Alameda County and is, therefore, in close proximity to all of the bay cities. Its western boundary line is within nine miles of San Francisco and adjoins Berkeley. Its area is 734 square miles, or about 444,491 acres. Its topography is semimountainous, with broad, rich intervening valleys. Besides the range of hills bordering the western and northern portions of the county, there are two ranges of hills running in a general northerly and southerly direction, with large productive intervening valleys watered by substantial streams. In the center of the county stands Mount Diablo, a rugged peak about 3,800 feet in height. The valleys of Alnamora, Pacheco, Ignacio, Clayton and San Ramon extend from Suisun Bay at Martinez on the north to the southern boundary line of the county beyond San Ramon. Numerous smaller valleys branch off from these, and the great San Joaquin Valley begins in eastern Contra Costa, extending from Mount Diablo on the west to the San Joaquin River on the east. The rich valleys afford an abundant food-supply for the squirrel population, while the wild hill lands shelter them in winter from the rains, and human and animal foes. The proximity of the county to the bay cities, which have until recently been plague-infected, and the constant presence of ships hailing from Oriental ports, in Suisun Bay, demonstrate how easily the infection could have been introduced into the county. The large area to be covered, the wide spread of the infection and the character of the terrain all combine to render the campaign exceedingly difficult. This is still in its infancy, but a sufficient number of infected squirrels have been found to justify the belief that we are dealing with a permanent focus for plague.

The beginning of the campaign was very difficult; a new field of sanitary activity was being entered, and there were no established precedents to act as guides. The herculean proportions of the problem and the great distances to be traversed were overwhelming. The difficulties in securing and distributing supplies and in collecting the squirrels and forwarding them to San Francisco all had to be met and overcome. In addition, the confidence of the people had to be gained, and it was necessary to allay their fears so that they would not feel that the county was going to be injured by the work. The matter of personnel was also one of considerable difficulty. Fortunately there were in San Francisco a large number of men who had been carefully trained in the plague campaign there and who could be relied on to execute their orders in an efficient manner and to meet emergencies without calling on the assistance of an officer. The ideal man for this class of sanitary work is one who is tactful, self-reliant, gentlemanly, a good shot, a conscientious worker, and one who is able to go ahead without the constant presence of an officer.

In the early part of the campaign, while the ground was still moist, eradicative measures were put in force, largely for the purpose of determining the efficacy of the various agents to be used in the extermination of squirrels. A careful study was made of their habits, and it was found that the squirrels spend the winters, that is, the wet months, in the foothills, and that there the young are born.

They are usually collected in colonies, and sometimes they dig very extensive burrows, honeycombing an entire hillside. The openings to the burrow are approached by little paths two or three inches wide, worn in the grass by the frequent passage of the animal. As a rule rather soft ground is chosen for digging the warren, but frequently the squirrels will burrow into hard adobe, and in several places they have dug tunnels in the soft limestone. The earth which is dislodged in digging the burrows is piled in a mound at the mouth of the hole. The tunnel, if the soil will permit, usually makes a sharp drop, and then points up hill a distance of two or three feet. It then forks, one main branch going to the storehouse and the other to the nest. Collateral branches lead off from these two main avenues and usually there are several exits. The nest is formed of straw and pieces of soft bark, and is usually alive with fleas. In the storehouse may be found grain, fruit, and several varieties of wild seeds, of which they are, apparently, very fond. These are transported to the storehouse in the cheeks of the animal. In late April and early May most of the young squirrels have grown sufficiently to travel, and an emigration into the low lands begins. This is not completed until late May, when the grain crops are harvested. By this time food in the hills has become relatively scarce, and the animals, descending into the valleys, subsist on fruit, garden truck and grain. In the former instance their activities are particularly pernicious, and they have frequently been seen to cut off a small branch laden with unripe prunes and drag it into their holes.

It is stated by those who have eaten them that at certain seasons of the year ground-squirrels are a toothsome delicacy. Certain it is that many people eat them regularly, and several families have been found who are in the habit of salting them down in large numbers and using them almost to the exclusion of other meats. In all probability the eating of squirrels is not in itself dangerous, provided they are well cooked, but the danger *lies in the handling of them prior to cooking, that* is, in skinning and preparing them. There are a large number of men who make their living by hunting these animals for the markets, and, until recently, large daily shipments were made. Realizing the danger of such a practice, Surgeon Rupert Blue invited the attention of the State Board of Health to it, and, at his request, a resolution was passed forbidding the acceptance of ground-squirrels for shipment by express companies and common carriers, unless accompanied by a certificate to the effect that they were intended for scientific purposes and carried in sealed metal cans. This succeeded, in a measure, in putting a stop to this dangerous business, but a large number of private hunters continued to come into the county. Dr. Blue then brought the matter to the attention of the mayors of Oakland, Berkeley and Alameda, with the result that the people were warned against the use of ground-squirrels for food. An inspector was also stationed at the Fish ranch on the tunnel road, which is the main thoroughfare into the county, with instructions to inform all persons passing with bags of squirrels of the danger to which they were exposing themselves. As a result, the practice of eating squirrels has very greatly diminished, and the market hunters have been obliged to seek other employment.

Two agents were found which gave good results in the poisoning of squirrels. The first of these was commercial carbon bisulphid. To use this, a piece of waste the size of an orange is saturated with the fluid, and the wet ball placed in the mouth of the squirrel hole. Earth is then tamped tightly on it so that the gas which is generated may have no opportunity to escape. All of the holes of the burrow are treated in this way. In some instances the ball is placed deeply in the hole and then ignited. This is more or less dangerous, as an explosion occurs, and, while the gas is thus disseminated to all parts of the warren, its action covers only a limited period of time, and is, therefore, not as certain as the first method mentioned. Experiments are now being made with carbon bisulphid shells, which may prove rapid and efficacious means of squirrel destruction. The shell is made of waxed paper which is loosely packed with waste. Leading into it on either side is an isolated wire, the bare ends of which almost meet in the center of the shell. Just prior to using, the waste is saturated with carbon bisulphid. When the electrical current passes through the wire it sparks across the gap, thus igniting the bisulphid and producing an explosion. If one of these were placed in each hole of the warren and the earth tightly tamped about it, and all discharged simultaneously, it is believed that the shock alone would be sufficient to kill everything in the warren.

Thus far none of the pumps for introducing bisulphid into the tunnels have proved ideal. Many of them are efficacious, but are very heavy and slow in their delivery of gas. It is believed that a light and simple apparatus can be made by attaching an automobile pump to a tube guarded by a valve, and leading to the bottom of a large square tin can, from the upper surface of which would lead a hose for carrying the gas into the hole. By pumping air through the can of bisulphid the gas would be generated and could thus be rapidly forced into the subterranean tunnels. Carbon bisulphid seems to be the ideal agent for the extermination of squirrels in a plague campaign, for the reason that it not only kills the squirrels, but also the fleas on them, and in the tunnels, thus precluding the possibility of infected fleas remaining to perpetuate the epizootic in another colony of squirrels subsequently occupying the same burrow. The chief disadvantages of carbon bisulphid are its high explosive power, its liability to corrode the cans in which it is kept, and its cost, 11½ to 12 cents per pound in the California market. It can not be used when the ground is dry and cracked, and can, therefore, be applied with success only during the wet or winter months.

Sulphur dioxid, if properly applied, would fulfil all of the requirements of an ideal agent for poisoning squirrels. It is cheap and non-explosive. It would kill the squirrel and his parasites. Thus far only one hand-pump for introducing the gas produced by burning sulphur has been found in the market, and an opportunity to experiment with this pump has not yet occurred. Compressed sulphur dioxid, if it could be obtained cheaply enough, would be certain and rapid in its action. In common with all other gases, however, it would be efficacious only when the ground is wet. The fluid obtained on cleaning Pintsch gas tanks has been recommended. It is cheap and said to be efficacious, but it is not easy to secure it in sufficient quantity for carrying on a work of this kind. Experiments are now being made with a view of determining the merit of this product as a pulicide. Should it prove an efficient agent in this regard we will have a cheap and effective weapon.

The second agent which gives good success is poisoned wheat. The poisonous agent used is either strychnin sulphate or cyanid of potassium, preferably a mixture of the two, applied to wheat with a little glucose, or other sweet material, and then dried. The appended formula may be highly recommended:

Strychnin	1. oz.
Cyanid of potassium	2 oz.
Eggs	1 doz.
Honey	1 pt.
Wheat or barley	30 lbs.

Stir eggs well, then mix in honey and again stir. Then put in dry powdered strychnin and cyanid and stir until well mixed. Put wheat in large box or can and pour in the mixture of poison and stir until it is well distributed over the wheat. Stir two or three times during twenty-four hours, then spread out and dry. Before putting it out for the squirrels add oil of rhodium 1 drachm.

This agent is very effective when the food-supply is limited, that is, during the winter months. Great care must be taken in the distribution of poisoned wheat lest domestic animals, quail and other birds be killed by it. It should all be placed in the squirrel hole itself, and never on the surface of the ground. This is especially necessary in pastures when the feed is short, because valuable cattle cropping the grass close to the ground are apt to take it and be killed. This not only entails considerable expense, but also incurs the everlasting enmity of the owner of the animal. It will thus be seen that the ideal time to carry on a squirrel eradicative campaign is during the rainy season, as the squirrels are then localized in the foothills, the ground will hold the poisonous gas and the reduced food-supply will cause the consumption of the poisoned wheat.

There is reason to believe that the booby owl, which is a constant companion of the ground-squirrel, occupying the same burrows with him, may play an important rôle in the dissemination of the epizootic. It is thought that this bird, flying from burrow to burrow, may carry infected fleas for long distances. If this be found true, the problem of the eradication of the epizootic will be greatly complicated thereby. Some of the ranchers of this vicinity firmly believe that the booby owl does not harbor fleas, and state that it will transport horse manure long distances for the purposes of lining its nest. Their contention is that the ammonia generated by the decomposing manure will inhibit the growth and multiplication of fleas. As yet no opportunity has occurred to disprove or verify this statement.

Phosphorus has not proved as useful in the destruction of ground-squirrels as in the poisoning of rats. It is dangerous to handle, and serious fires may be started with it. After a few days' exposure to the open air and the bright sunshine it quickly loses its toxic power, and it is, therefore, not recommended for this work.

When there is a sufficient fall of water, flooding the squirrel warren will drive the squirrels out very effectually. If men are stationed around the edge of the colony with guns or clubs great numbers may be slain; but flooding is useless unless this is done, because the squirrels will simply migrate to the high lands, to return as soon as their burrows are dry.

It has been hoped that some use might be made of the natural enemies of the squirrel in this campaign, but no one of the known natural enemies is ideal for this purpose. The coyote, wolf, fox, badger, skunk, mountain lion, gopher snake, and red-tailed hawk all prey on the squirrel, but each is open to some objection. This matter is, however, being carefully studied out, and some plan may be evolved whereby use can be made of these means of killing squirrels.

Several varieties of traps have been experimented with, but none have proved very successful. A squirrel is a very wary animal, and will not enter its hole if it sees anything unusual therein. So simple a thing as a ball of paper placed in the mouth of the hole will cause the squirrels to abandon that particular runway. Experiments are now being made with snares. These are made of fine piano wire, and it is hoped that in this way a large number of ground-squirrels may be captured alive. This will afford the laboratory an opportunity to study the susceptibility to plague of squirrels from an infected locality, and a few may be captured in the early stages of plague, thus rendering it possible to study the natural form of the disease at close range.

As a result of these discoveries it was decided by Surgeon Rupert Blue, who is in command of the plague campaign on the Pacific coast, that the work of the ensuing summer should consist entirely of scouting, with a view to determining the places in which infection occurred, and the percentage, if possible, of squirrels so infected. A number of men were, therefore, sent into Contra Costa County with an officer in charge. They were stationed, usually one man in a place, at what were considered the strategic points. Each was supplied with a double-barreled, 12-gauge shotgun, a cleaning rod, canvas knapsack, canvas-covered aluminum canteen, ammunition, squirrel tags, cans, chloroform, solder, indelible pencils, report blanks and stationery. A folding cot was issued to each man. The government provided subsistence for employés, but the latter were obliged to provide themselves with blankets, hobnailed shoes and other necessities.

It has been found, after considerable experimentation, that the double-barreled, 12-gauge shotgun is the best agent for shooting squirrels. These are light and, therefore, do not overburden the hunter, and, when well choked, are very effective up to fifty yards. As a matter of economy, however, the hunters do not usually shoot squirrels at a longer range than thirty yards. Rifles have been experimented with, but their use has been found impracticable. The 22 automatic is a handy gun for this purpose, but too frequently the squirrels shot by it escape. The 25-20 kills the animal most often, but it is a high-powered weapon, and the bullet will travel a considerable distance after having passed through the squirrel. This makes its use a menace to man and stock, and it is, therefore, not suitable for this sort of work.

The matter of ammunition has also been very carefully worked out, and it has been found that 3¼ drams of bulk powder and 1⅛ ounces of No. 8 soft shot make the most effective charge. Ground-squirrels are very hard to secure after having been shot. Frequently, even though badly mangled, they will crawl into their holes and thus escape. The ideal charge for securing ground-squirrels for purposes of examination is that which gives the maximum shock with the minimum laceration of the tissues. No. 8 shot is large enough to fill these requirements. It has been our experience that squirrels are most often secured when they are shot on the run, and that almost invariably when they are shot sitting up they will fall into a hole and thus escape. By shooting at the running squirrel the hunter has the double advantage of striking the animal when it is spread out, while at the same time he may choose the place where he wishes it to fall.

The squirrels are secured as soon as shot and the tags immediately attached. This is necessary because they will sometimes revive and crawl away, or the hunter may lose track of them and waste considerable time in hunting for them. If they are tagged as soon as shot there is no danger of tagging them wrongly, and the handling is reduced to the minimum. At the beginning of the campaign it was thought that the best way to secure plague-infected squirrels would be to make a careful search for their dead bodies. The employés were, therefore, instructed to make careful search for dead squirrels in and around colonies in which they were hunting. Out of sixty-seven thus found, not one has proved to be infected. This method has not, however, been abandoned, but little is expected from it, and it is thought that it is not improbable that the plague-stricken squirrels die in their holes.

Dogs are now being trained for the purpose of retrieving squirrels. This will save the hunter a great deal of work, and will enable him to secure almost all of the squirrels which he wounds. It has been found that the early morning and late afternoon are the best times of day to shoot squirrels. They ordinarily do not come out of the holes when it is very warm, very cold or very windy. It is not profitable to hunt in the same colony for more than two or three days at a time, as the squirrels soon become very "gun-shy" and take to earth as soon as any one approaches. Under ordinary conditions a hunter should shoot and secure at least 30 squirrels per day, although when they are very numerous the day's bag may reach 60 or 65. In one instance one man shot 86 in eight hours. It has been found that unless the hunter wears some protection for the shoulder it will become very badly bruised by the recoil of the gun. The best agent to prevent this is a pad of soft felt an inch in thickness, such as is used beneath horse-collars.

With a small number of employés we have been able thus far to send to the plague laboratory in San Francisco for examination an average of 2,000 squirrels per week. It is hoped that with a small increase in the force now at work this may be increased to 3,500 or 4,000 per week. These are taken from all parts of the county, it being the principle that for the present the work shall consist of taking samples of the squirrel population so that we may be able to outline with some degree of accuracy the area at present infected. Each squirrel is tagged to show where, when, how and by whom captured. Usually the label also bears the name of the nearest town, so that if the squirrel should be found infected it will be easier to locate the particular ranch on the map. This is also necessary because there are so many ranches in various parts of the county bearing the same name.

Supplies are secured on contract, and are distributed to employés on requisition. It is not always an easy matter, but a small automobile is used and fifty or sixty miles are covered every day with a load of ammunition, cans and other supplies. By requisitioning early no time is lost by employés in waiting for shells and other munitions.

Employés have been cautioned as to the danger of handling squirrels, and the opportunity to receive Haffkine's prophylactic has been offered them. Several of the hunters have taken this immunizing treatment. All employés have been warned not to thrust their arms down the squirrel tunnels in an endeavor to recover animals which they have wounded. There is not only the danger of being bitten by the squirrel, but some infected fleas may also be picked up in this way. Another point not to be forgotten is that there are sometimes rattlesnakes in the holes. In fact, several employés were nearly bitten in this way. It has been found that a heavy piece of wire with a sharp barb about an inch long on the end is a very effective instrument in extracting wounded squirrels from the burrows. Each hunter carries in his knapsack a ball of waste saturated with chloroform. This is for the purpose of killing the fleas on the squirrels.

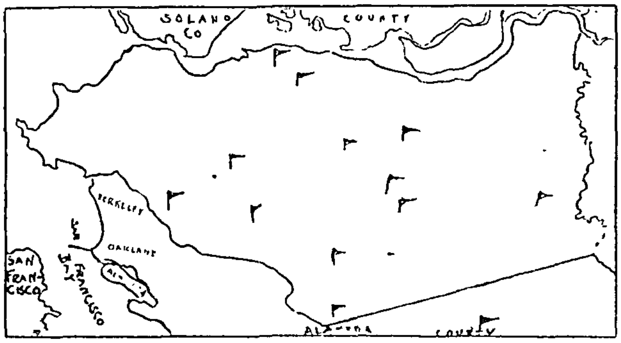
Each evening the squirrels are placed in tin cans specially provided for the purpose. In the can is placed 75 c.c. of commercial chloroform for the purpose of killing fleas; the lid is then tightly applied and carefully sealed with the solder. The can is then tagged and sent by express to the plague laboratory in San Francisco. It will thus be seen that every precaution is taken to protect expressmen and other persons handling the cans. In hot weather the squirrels must be rushed to the laboratory with the greatest expedition, as they are likely to decompose rapidly and generate considerable gas, which will blow off the covers, no matter how tightly they may be secured. This causes complaints on the part of the express companies and their employés. In many instances, however, it is very difficult to forward specimens prior to their decomposition. One hunter stationed in an isolated part of the county makes it his business to know whenever the ranchers in his vicinity are going to town, and gets them to carry his squirrels to the nearest village. There they are delivered to a foreman who ships them by stage to the nearest railroad; thence they are taken direct to Oakland, and by ferry to San Francisco.

Where two or more men are hunting in the same district (or where the bag is unusually large) large milk-cans with especially prepared rubber gaskets are used The lids are also secured by padlocks, one key of which is kept by the man sending the can, the other remaining at the laboratory. The small cans are used but once; the large cans are returned by express.

On the arrival of the cans in San Francisco they are immediately transported to the laboratory by a special messenger with a wagon. They usually arrive in time so that they may be examined within twenty-four hours after they are killed. When the squirrels arrive at the laboratory they are first liberally sprinkled with chloroform, after which they are given a bath of bichlorid of mercury, 1 to 1000. They are then piled on a large lead-topped table. One employé tacks the squirrels to shingles and passes them to a second laboratory assistant, who makes a record of the tag and gives the shingle a number, so that if the tag should be lost it will be possible to tell where the squirrel came from in case it should be found infected. The squirrel thus prepared is passed to other men who have become expert in opening small mammals through their great experience in handling rats during the San Francisco plague campaign. These men are very skilful in recognizing the gross lesions of bubonic plague, and as soon as a suspicious animal is found the dissection of it ceases. The attention of the bacteriologist is called to the squirrel, and in case he is unable to look at it immediately it is covered with a damp towel for the purpose of keeping off flies, should any have found entrance to the laboratory. The dissection is then finished by the medical officer in charge of the laboratory, who dictates to a clerk the findings in each particular case. They are noted on a card which becomes a part of the card-index system of the laboratory. Inoculations are made into guinea-pigs, and the usual cultures planted. All squirrels are carefully examined by the medical officer in charge of the laboratory, but so expert have his assistants become that on two occasions only have they failed to lay aside squirrels which subsequently proved infected. The value of the pathologic findings in the recognition of plague is thus very clearly demonstrated.

As soon as a suspicious or positive squirrel is found the medical officer in charge of the field operations is notified. It is the policy to discontinue work on any colony of squirrels which has presented a considerable degree of infection, it being felt that the present object of the work in that particular locality has thus been accomplished. The accompanying map shows the locations in which infection has been found. It will be noted that they are widely separated.

In all, about 250 infected squirrels have been found to date (Oct. 1, 1909), some having been found in almost every portion of the county in which the men have been at work. It is planned that in the autumn, when the suitable time for poisoning squirrels arrives, and the ranchers have the time to take up the matter, a general campaign of education will be instituted, and an endeavor made to enlist the cooperation of every person holding land in the county. It is hoped that poison may be issued gratis, and that the ranchers will distribute it under the direction of inspectors of the service. The State Board of Health and County Board of Supervisors cooperate in every way in the prosecution of this work.



Outline map of Contra Costa County and contiguous counties. The small flags indicate infected areas.

The commercial aspect of the problem is one which will interest the entire farming population of this region, and while they may not be enthusiastic over the campaign from the point of view of the public health, they are keenly alive to the fact that the eradication of the squirrel means the prevention of a tremendous annual monetary loss. It is, therefore, felt that there will be little difficulty in enlisting their cooperation.

The work which is now going on is directed at the eradication of a permanent focus for plague, and it is felt that the successful completion of this undertaking will rid America of a slumbering volcano of plague liable to eruption and great devastation at any time. This is a departure into a new field of sanitation and may be considered an advance in preventive medicine.

Pathologic Menopause.—H. F. Pitcher, Haverhill, Mass., at the recent meeting of the American Electro-Therapeutic Association, stated that when the ovaries begin to atrophy and menstruation ceases while the nervous energies and nutritive system continue active, causing nervous irritability and vasomotor disturbances, the positive static breeze should be used until the nervous tension is relieved. The negative static breeze may be used if the patient becomes apathetic with a tendency to melancholia, followed by a strong spinal vibratory stimulation. He asserted that he has known mental aberration to clear up from this mild form of treatment. Malassimilation and autointoxication as a result of faulty elimination caused by passive congestion of the excretory organs, should be treated with the static wave current over the spinal region and abdomen. This aids metabolism and eliminates toxic material. When cerebral symptoms and vasomotor disturbances are excessive in plethoric patients, better circulation and tone in the pelvic organs may be produced by the static wave current. If the patient is of nervous temperament with sensitive pelvic nerves, the negative pole from the direct current is used in the vagina. On the other hand, prolonged menstruation or excessive uterine hemorrhage is controlled by the positive direct current, either vaginal or intrauterine, or by use of the Roentgen ray.

FOUR GENERATIONS OF AMERICAN GOUT *

ROBERT N. WILLSON, M.D.
PHILADELPHIA

The following series of four instances of chronic food-poisoning in four successive generations is submitted for its diagnostic interest, as well as because of its value in suggesting for therapeutic and hygienic attention the ground condition underlying similar obscure cases:

Case 1.—The patient first came under my medical observation in 1901, when in her eighty-eighth year. She had always been a full eater, but did not consider herself unusual in the matter of appetite. The joints of the fingers and toes showed unmistakable, gouty changes, and the history given was that of an increasing disability of these small joints. On Oct. 10, 1901, while stepping from a carriage she felt a severe pain in the right knee, which gave way, letting her down on the ground. She was in great pain; the knee when seen by me was hot and considerably swollen, and there was some fluctuation evident above and outside the patella. No other joints were involved. On October 12, 1901, both knees and ankles were hot, swollen and tender. This condition gradually subsided under practical starvation and free evacuation of the bowels, and within a few days entirely disappeared. The temperature was never above 99 F.; the heart showed no sign of involvement; the urine was high-colored, full of urates, and contained a faint trace of albumin.

From that time until the death of the patient one year ago, at the age of 93, there were recurrent mild attacks of a similar nature, invariably controlled by and through the dietary, and by artificial evacuation and cleansing of the intestinal tract. Very frequent had been the occurrence of urticaria, sometimes synchronously with the joint involvement, often alone.

A vegetable, restricted diet enabled the patient to remain entirely free from symptoms, but was so seldom adhered to that the discomfort consequent on an oversuppply of food was usually present. This varied according to the gravity of the offense (measured in terms of food quantity) and its duration, far more distinctly than with the variation in the kind of food.

Case 2.—The patient was an otherwise healthy man, aged 61, of sedentary habits, an excessive smoker, and an admittedly rapid eater. His food-supply, while always generous, never amounted to an apparent excess for the average man. He first came under my care in 1900, shortly before I saw and studied the case of his mother, just described. In 1892 he had been in bed several months with sciatica, following an accidental blow on the head. Since that time more markedly than before he had noticed a fulness of the abdomen, dizziness, belching, fugitive pains in the head, general discomfort, and a sense of heat throughout the body. The occiput and nape of the neck felt heavy, and sometimes even ached. There was considerable flatus and discomfort in the abdomen. The mouth "tasted bad," lights were seen dancing before the eyes, and there was some palpitation. The urine was high-colored and full of uric acid and sodium urate crystals.

Since first studied by me there have been many disappearances and just as many recurrences of this picture. Occasionally patches of eczema would appear over the dorsal surface of the hands, or on the arms. Once a large area (the size of the palm of the hand) appeared swollen, red and tender, in the left hypochondrium, and subsided without notice, as though an angioneurotic edema. There has been considerable stiffness and heaviness in the right leg, particularly from the knee down. This he attributes to the accident and to the blow on the head already noted. Occasionally the movements of the ankle and foot "have not been easy or natural." "This has always passed away." There has occasionally been an aching of the shin-bone and the calf of the leg, and a numbness of the toes. All of the symptoms have recently diminished and many have disappeared.

In May, 1905, during a series of symptoms similar to those just narrated, there appeared a crop of suppurating blebs between the toes of both feet, also a few on the under surface of the toes, and in the cracks and crevices of the under surface of the feet. First seeming abrasions, then blebs, then pustules made their appearance. Lymphangitis of the right leg followed, red lines running to the groin. The patient's condition was a distinctly septic one for two days and then settled to the normal. On milk diet and in bed the feet healed and in a week's time appeared well. Immediately on the resumption of solid food the blebs and pustules would occur, to subside again with its withdrawal. There was an excess of acid, offensive perspiration between the toes, and the tissues seemed to break down under its influence unless kept constantly clean. On diet, rest, complete withdrawal of the tobacco, and free evacuation of the bowels, this condition receded, and convalescence was secured, though only after a siege of three months' duration. The urine during this period showed the same concentration as on each previous occasion; also the precipitation of uric acid and its derivatives. In April, 1909, there was a beginning of a similar involvement of the toes and feet. With the previous experience to guide the line of treatment, however, the duration of the condition was brief, and at the end of a fortnight the skin surface appeared and remained normal.

The indefinite discomfort and the local symptoms on the skin of the body have occasionally recurred, but like their congeners, those of the toes and feet, all have yielded to fasting (tobacco and food) and to intestinal asepsis.

Case 3.—This has been my own, and of especial personal interest, in the light of the two preceding pictures in my immediate ancestors. During boyhood I was able to eat inordinately, and no doubt, as most boys do, so I did. There is little doubt, moreover, that, boy-like, the method of eating was hurried and the mastication imperfect. Nothing untoward transpired in a health record singularly free from need for medical attention until the year 1902, when, while in the midst of a tennis match, I found myself unable to run because of a sharp pain in my right hip-joint. The next day this pain had nearly disappeared, and to such an extent that I was able to play through the tournament.

Frequently through that summer the pain recurred, always suddenly, usually during active exertion, and as a rule continuing for the greater part of a day. Usually it was in the hip, sometimes in the right knee. Rarely the right ankle felt heavy and painful. There was never swelling, and the joints were neither red nor hot. I next noticed that in the morning the hands felt puffy and swollen, the eyes tired, and the throat and pharynx stiff and even painful. The urine was normal and at no time then or since has contained either uric acid crystals, urates (solid), or albumin. Finally, one night after severe exercise, I noticed that although before dinner perfectly free from pain, I rose from the table stiff in the right knee and ankle. For the first time I associated the joint pains with the ingestion of considerable quantities of food, especially after severe exercise, and began to experiment accordingly. I found that up to a certain limit I could eat any and every kind of food. As soon as that limit in quantity had been passed the old joint symptoms, plus those of the face, hands, eyes and throat, would all make their appearance, and remain for a time corresponding to the excess of food. I found that fasting would relieve the distress, and that purgation would do away with it almost at once. There seemed to be little doubt either as to the etiology, pathology, or treatment indicated. A dietary régime was instituted that absolutely removed the difficulty and for a time prevented its return.

Two years ago there occurred another series of symptoms which proved equally perplexing, and was stupidly enough attributed to an entirely mistaken cause. I had been in the habit of using the first joint of my left forefinger as a pleximeter under a metal plexor, in order to employ to advantage both the sense of hearing and the perception of resistance to the stroke. On the morning following a banquet I noticed a crop of tiny blebs surrounding this joint, and a sense of heat (not pain) in the skin and overlying tissues. My pharynx was stiff and sore, my eyes were watering, I suffered *from a* profuse coryza, I sneezed incessantly, and, what seemed exceedingly strange at the time, my hands and feet were too large for gloves and shoes. The urine was absolutely normal. In a day every symptom had disappeared; even the joint of the forefinger had become normal. More than once after this the blebs and slight swelling of this joint reappeared, sometimes with, sometimes without the attendant train of supposedly influenzal symptoms. Invariably the occurrence followed a dietary indulgence between meals, and finally the association became too striking to ignore. I again began to experiment, as frequently as I could persuade myself to endure the discomfort of an old-fashioned influenzal attack. As certainly as I exceeded my heretofore perfectly safe limit, just so inevitably did I pay the penalty. A whole day would go by. Then a general feeling of muscular soreness and exhaustion would appear. The feet and hands would begin to feel swollen, and within twenty-four hours, or much sooner if the excess of food was large, the skin of the first phalanx of the left forefinger would parch and dry up, and later the digital phalanges of the first and second fingers of the left hand also. The dried skin would break out in blebs, with an intense itching that subsided only with a bowel movement, or with distance from the last ingestion of food. The pharynx would become red and granular; it was painful to swallow; muco-pus formed in the nasopharynx, and very frequently the voice would become husky to an extent that was as embarrassing as ridiculous, the cause being known. My nose would run and the tears flow as though I was suffering from an acute cold. On more than one occasion the irritation of the conjunctiva simulated one caused by a foreign body. The secretion varied from a clear serum to a true laudable pus. Almost invariably the ears felt full and uncomfortable. On one or two occasions there was a scaling and cracking of the skin between the toes. All of these symptoms, especially those experienced locally in the feet and hands, seemed to be exaggerated by any severe nervous excitement. Even when the blebs and swelling in the superficial tissues of the phalanges were subsiding, the nervous stimulus of a public discussion or speech, or of the presentation of a scientific paper, or even the stress and hurry of a crowded day's program, would tend to relight their activity, or at least to delay their disappearance. Following a free evacuation of the bowels there was almost immediate partial relief. Sprays, local applications and the internal administration of drugs, made matters only worse. Fortunately the conditions were such as naturally to discourage eating, because the appetite never waned.

---

* Read at the College of Physicians of Philadelphia, June 2, 1909.

Finally it became apparent that the quantity of food ingested in the twenty-four hours and that alone was at fault. From that moment the task became simple, though as difficult as it was plain. If too much was being eaten, less would and must suffice, even if it implied, as it does, a military diet. It appeared that there had developed either a tendency to the need of a diminishing amount of food in spite of a persistent appetite, or a more and more evident contraction in my ability to assimilate food-products. That the latter is not the correct explanation of the symptom-complex, which I can produce at will and as readily prevent, seems apparent from the perfect maintenance of health and vigor and bodily weight on an amount of food sufficiently low to prevent discomfort and subjective symptoms. That a diminished need plus a family idiosyncrasy best explains the phenomenon became laughably and painfully clear when the tendency reasserted itself in my child.

Case 4.—This has been studied in my little girl of 4 (now 5) years, a high-strung child, always under nervous tension, who during the past twelve months has had repeated attacks of a type that her mother has labelled "cold," "grip," and everything else except the proper diagnosis, which only within the very recent past has she been willing to admit into consideration. Always overfed, like every other American child of Anglo-Saxon parentage, this little girl has, without warning, repeatedly become hoarse, has coughed day and night, has sneezed when not coughing, and run from eyes and nose until the handkerchief supply has found an end. Relief has been obtained when, and only when, the intestinal tract has been emptied from one end to the other and food altogether withdrawn. Skepticism became so intolerant that I finally challenged the mother to the experiment of deliberately overfeeding the child. She thereby produced a full-fledged, old-fashioned cold that would ordinarily require a week's sojourn in bed. Castor-oil and starvation, with the child at rest in bed, furnished a speedy cure. I have so often watched the process of overfeeding in this case result in the gradual production of the now (to me) classical symptoms, that I can nearly calculate their time of appearance by the amount of food administered.

That this case is not *sui generis* finds ready witness. Only to-day there was sent to me from Virginia a little girl of 12 with the history of a long-standing cold, catarrh of the nasopharynx and constant sneezing. I found her chest and abdomen normal, the lungs and heart absolutely sound. The tonsils were large, and from the nasopharynx dropped steadily a yellowish muco-pus. The mother stated that the child had a poor appetite, but on inquiry from the child I learned that the dietary of the day before had been as follows. Food actually eaten: breakfast, one orange, a plate of cereal, beefsteak, three griddle-cakes and syrup, a glass of milk and one slice of bread and butter; dinner, two helpings of meat, two helpings of potato and of one other vegetable, bread and butter, pickle, radishes and dessert; supper, meat, vegetables and fruit. While in my office this child sneezed several times. Her nasal and pharyngeal mucous membranes were slightly reddened, but otherwise normal. While the case has not been studied to its end, there is little doubt in my mind that this Southern descendant of our English ancestors is suffering from an inherited overappetite and from the need of a lessened food supply.

The danger from such knowledge as is gained through a superficial study of the above series of cases is apparent. It will furnish a strong temptation to the practitioner to term every cold gout, every influenza food-poisoning, every ache and pain lithemia, every joint swelling an excess of food. On the other hand, carelessness of the significance of signs and symptoms leads to disaster. A few days ago I saw in consultation a trained nurse with a tuberculous apex. Tubercle bacilli have since been found in her feces, and a positive tuberculin reaction has been obtained. There was neither a cough nor a particle of sputum to suggest a pulmonary involvement. The case was sent to me as one with a cardiac lesion.

I publish these records, my own among the number, for what they are worth in interest and value as bits of home study and observation and as pointers to the need of a discriminating care in diagnosis. Not without practical interest is the evident association in at least two of these cases of two distinct influences, the toxic and nervous, in the production and accentuation of symptoms. If no other lesson were taught and learned it would be of advantage for us to understand that not every chronic cough and expectoration can be safely regarded as tuberculous in origin; that a moderate amount of food may be an undersupply or an excess for the given individual; and that many a laryngitis and partial aphonia may be rationally attributed to the diet, and cured by a hygienic regime.

1708 Locust Street.

Infant Feeding.—The number of women unable to nurse is much less than is popularly supposed. Madame Dluski, in a thesis delivered at the Baudelocque Clinic, Paris, expresses the opinion that among 100 healthy women, when the necessary conditions of food and rest are present, 99 are actually able to nurse their offspring.—J. M. Connolly in *Hygiene and Physical Education.*

Clinical Notes

A NEW AND STABLE SOLUTION OF GENTIAN VIOLET FOR THE GRAM STAIN

ROBERT KILDUFFE, M.D.
PHILADELPHIA

Unfortunately for the simplification of an often complex problem, we now know that bacteria cannot be divided, as was once thought, into two great classes of Gram-positive and Gram-negative. It is true that many of the varying and contradictory statements on this head may be explained on the score of variations in technic, such as the length of time the stain and the alcohol were allowed to act, and the age of the culture experimented with; but it is nevertheless a fact that organisms repeatedly and consistently found to be Gram-negative will sometimes take the stain very well.

Thus, Zimmermann[1] found that all cultures of the *Bacterium fluorescens* stain well in young cultures; and Lehmann and Neumann[2] found that three out of twelve cultures of the same organism stained beautifully, yet this is a species spoken of in the literature as Gram-negative. The latter workers also stained the bacillus of symptomatic anthrax; and the *Bacillus tenuis,* at first Gram-negative, on a later test with the same technic, stained very well. They state, finally, that "a separation of the individual genera and varieties by Gram's stain now seems scarcely at all possible, since there are found within a single genus all stages, from those which stain well to those which stain poorly or not at all."

Notwithstanding these results, Gram's stain remains a valuable routine procedure, and one which is capable of conveying much information of interest; and, in so far as the gonococcus is concerned, it is a means of differentiating; at all events, it is a measure extensively used.

An intrinsic difficulty, and one usually most apparent just when it is desired to use the stain, is the tendency of the gentian violet solution to decompose, especially in warm weather, with the resultant loss of the entire solution and the time required to make a new one. Having had this happen with annoying frequency, I desired to find some way of obviating the difficulty.

Dr. E. Burville Holmes[3] has had success with the addition of 3 to 5 per cent. of glycerin to the stain, which he keeps in a dark, cool place. This procedure in my hands has not met success, the stain, in some instances, apparently deteriorating even more quickly. A search through the literature at hand revealed very little of interest.

Lehmann and Neumann[3] mention Czaplewski and E. Frankel as recommending, instead of anilin water, a 2.5 per cent. phenol water. This is stated not to decompose so soon as the anilin mixture. Muir and Ritchie[4] also recommend phenol water (1 to 20) and cite Kuhne's method in which the gentian violet is replaced by crystal violet in 1 per cent. ammonium carbonate solution. Beyond this nothing could be found.

After adding various substances to the staining solution without result, the question of a new solvent was taken up. It was found that a weak solution of formalin answered the purpose admirably. To make the solvent, 5 c.c. of commercial formalin (40 per cent.) are added to 95 c.c. of distilled water.

The stain can be made in the usual proportions of 16 parts of the stock solution (saturated alcoholic) of gentian violet to 84 parts of the solvent, or it can be made, as I prefer, in the proportion of 25 parts of the stock solution of gentian violet to 75 parts of solvent. Such a solution has been kept for over eight months in open test-tubes exposed to light and varying temperatures without deterioration.

It can be used just like the usual anilin solution, and decolorizes readily on the addition of alcohol. Should there be any doubt as to whether the preparation has decolorized completely, a drop of anilin-xylol (equal parts), followed by alcohol, will remove any uncertainty.

The advantages of the solution are obvious. It will remain good until the last drop is used; thus it is economical. No modification of the technic is necessary. Molds cannot grow in it. It will keep indefinitely. Preparations made with it are sterile—an advantage not to be overlooked if one is dealing with plague, glanders, or other virulent cultures.

It is hoped that the solution will prove as useful to others as it has been to me in the saving of time, patience, and materials.

UREMIA, SEQUEL TO SCARLET FEVER

VENESECTION AND RECOVERY *

SCOTT P. CHILD, M.D.
KANSAS CITY, MO.

Acute uremias, dependent on intoxication from any cause, are of such uncertainty of occurrence and so serious in results that the report of a specific case with its treatment and recovery is not without justification. The case in question was sequel to a typically severe infection of scarlet fever which terminated on the sixteenth day by fall of temperature without complication, with no deficiency in urinary secretion or appearance of albumin.

The initial signs of the attack were first observed four days after the fall of temperature, with the child, a previously healthy boy of 7 years, in bed and on a liquid diet. In the evening of the fourth day, following a cup of broth, the patient was nauseated, but without emesis, and soon fell asleep. In the early morning following, when he had been thought to be sleeping, he was observed to be twitching about the muscles of the face, and to be unconscious instead of asleep. At 8 a. m. the rectal temperature, which had not been above 99 F., rose to 99 1/5 F., and at 2 p. m. was 104 2/5, with a bounding, somewhat irregular pulse of 116, from which rate it gradually rose, with marked irregularity and intermittency, to 136 at 11:30 a. m. of the following day.

Then, for practically twenty-two hours, hourly convulsions were observed and recorded, of varying severity, at times local, but usually general, noticed especially in the muscles of the face and extremities, though there was no marked retraction of the posterior muscles of the neck and no true opisthotonos. Acute and irregular strabismus of both eyes frequently occurred. The only contractures suggestive of focal involvement was, toward the latter part of the attack, the almost continuous twitching of the toes of the left foot. This was not observed in the other foot or in the hands. The child was unconscious during the entire period of the convulsions, for a greater part in a state of coma, though at rare intervals delirous and irritable, if touched or spoken to.

The temperature, during the attack, after rising to 104 2/5 degrees per rectum, varied between that and 103 2/5 degrees. The influence on the circulatory system was most pronounced.

---

* Presented before the Jackson County (Mo.) Medical Society, Jan. 13, 1909.

the pulse was markedly irregular and intermittent, varying from 116 to 136, of high tension, though of uncertain quality at times. The heart sounds were, of necessity, not observed closely during the convulsions, but toward the last were distinctly muffled, with a later developed systolic murmur, which lasted well into convalescence.

Edema, which was not present previous to the attack, soon began about the ankles and joints, and was especially marked about the shoulders, neck and face, though there was, apparently, no effusion into any of the serous sacks. The entire glandular system, including that of the skin and kidneys and of the alimentary tract, was inactive so far as any clinical evidence was concerned, for twenty-four hours, there being no perspiration, natural or induced, and no secretion from the mouth or bowels. At the end of twenty-four hours 2 ounces of urine were removed from the bladder by catheter, the only amount secured; this amount was probably residual urine, rather than a renal secretion during the attack.

Toward the last of the convulsive period, between 8 a. m. and 11 a. m., the coma became more and more marked; the skin of the face was very dusky, the body and extremities mottled, and the lips cyanosed. The respiratory rate, which had been from 20 to 26 and quite regular, grew slower and more difficult until characteristic Cheyne-Stokes breathing, of eight to ten respirations a minute, resulted.

The special senses, especially vision and hearing, showed their involvement as the patient later grew conscious and rational. It was interesting, though somewhat tragic, with the question of systemic and local result in the balance, to see the little patient strain his head toward a sound or voice that he heard, but did not distinguish, and then say, "I do not see you"; then, still later, failing to recognize a face or form, speak of the light burning above his head, and finally as he recognized his mother and others about him, show evidence that his special senses were being restored.

This was, in brief, the picture which presented itself for about twenty-eight hours, while Nature unassisted, though not without attempt to assist by the common and generally accepted measures, fought in her effort to overcome an unknown and suddenly developed enemy in her own structure. The measures resorted to during this attack of uremia had for their purpose the endeavor to lower the local and general congestion and circulatory pressure on nerve centers and in vital structures, and to eliminate from the whole system the known retained wastes which Nature was now unable to discharge, and other products of unknown origin and character, but extremely toxic in their influence on all animal tissues, the latter the probable cause of the convulsions.

To be specific, there was endeavor to stimulate all the emunctories which had ceased to act, and to stimulate and to bring to a state of equilibrium a very much disturbed circulatory system. No stress was placed on controlling the nervous system *per se*. Hot packs were regularly and continuously applied for purpose of provoking diaphoresis; calomel and Rochelle salts, with high enteroclysis of physiologic salt solution, were used, with hope both to eliminate and to dilute the toxins present and to assist in equalizing the circulation, and, if possible, to produce diuresis indirectly. In addition, nitroglycerin and digitalin were administered hypodermically for the peripheral circulation and diuresis. With a few other measures and minor details, such was the therapeusis for twenty-four hours—with results clinically negative. No diuresis occurred; the purging and enteroclysis showed no evident stimulation; perspiration did not occur, the skin remaining hot and dry. The circulation and respiration meantime growing weaker, venesection was advised and performed; the median cephalic vein of the right arm, after careful antisepsis, was opened and the child bled of between 8 and 10 ounces. This was at 11 a. m. with the child *in extremis*, a temperature of 103 2/5 degrees, pulse irregular, high tension and 136, with Cheyne-Stokes breathing, eight respirations to the minute; delirium and muscular twitching.

No convulsion occurred during or after the withdrawal of the blood. At 3 p. m. the breathing was 22, regular and easy, the temperature 102 3/5 degrees, the pulse 124 and more regular; the body was covered with perspiration, the child began to answer questions and was less irritable; at 7:45 p. m. 5 ounces of urine, loaded with albumin and casts, were removed by catheter.

From the time of removal of the blood no serious symptoms occurred and steady improvement followed hourly; hot packs, pilocarpin hypodermically, calomel and salines, with a liquid diet, were continued for twenty-four hours; this treatment then being gradually given up, since all the emunctories and in general the body functions were approaching the normal. On the third day, 52 ounces of urine were voided voluntarily, and natural and freely induced perspiration ensued, with marked improvement in the urinalysis. At the present time, several months later, an apparently perfect recovery has occurred.

603 Bryant Building.

COMPOUND FRACTURE OF THE INFERIOR MAXILLA *

W. ARMISTEAD GILLS, M.D.
Assistant Surgeon, Seaboard Air Line Railway; Adjunct Professor Anatomy, Medical College of Virginia.
RICHMOND, VA.

The exposed position of this particular irregular bone, as it is classed anatomically, explains the frequency with which the surgeon is called on to treat it. Fractures of this bone are always due to some form of violence, or to the extraction of a tooth, the usual seat of fracture being the anterior part of the body of the bone, between the mental foramen and symphysis, which is obviously in the line of least resistance, although no part of the bone is free from the possibility of a fracture. The case to which I invite attention bears out this statement anatomically.

Patient.—A very robust negro, aged about 30, an employee of the Seaboard Air Line Railway, blacksmith by trade, presented himself at my office not very long since. An hour before he had been struck with a sledge-hammer by a fellow workman on the right side of the chin.

Examination.—Patient was unable to articulate distinctly; saliva was dribbling, the teeth were uneven; there was an open wound just over the mental foramen externally, with a large spicule of bone projecting; the canine on the right side was very loose. On placing my finger in the mouth I detected the presence of bone, which was rather sharp and mobile, but fortunately had not lacerated the mucous membrane. The fracture was complete, transverse in the long axis of the mandible, with little, if any, antero-posterior obliquity. The displacement could be determined easily by inspection.

Treatment and Clinical Course.—The case was seen so early that very little swelling had occurred. Its reduction was easily effected by manipulation. The spicule of bone having been returned, the wound, which for obvious reasons was not sutured, was made aseptic. Although some of our best men advise the removal of the loose teeth at the point of fracture, I did not do so, but permitted the canine to remain; and this treatment was followed by good results. Retention of the fragments in position was sufficiently secured by bandaging the lower jaw to the upper by a single figure-of-eight chin and head bandage. Patient was sent to the Memorial Hospital and permitted to walk around in his room. Feeding with fluids was satisfactorily accomplished through the natural irregularities of the dental arcades, as there was no space due to the loss of teeth. The wound, being dressed daily, had practically healed on the fifth day. I made the bandage sufficiently tight to prevent the patient's opening his mouth and instructed those in attendance not to permit him to talk, but in the event it became necessary, to educate him to talk through his teeth, so to speak. His mouth was rinsed daily with antiseptic solution. At the end of the sixth day he insisted on going to his home, which was in the city; to this I gave my consent, but rather reluctantly, with the promise that he should report to me on alternate days, which he did and at the expiration of two weeks the bandage was removed, not to be replaced. Careful examination at the seat of the fracture failed to reveal any deformity. The patient now began to partake of semisolid food, reporting to me every third day during the third and fourth weeks; at the expiration of the fourth week he was masticating anything he desired and was dismissed as cured; in other words, I did nothing for him except for the first two weeks.

---

* Read before the Association of Seaboard Air Line Railway Surgeons, Raleigh, N. C., Oct. 19, 1909.

While I do not wish to decry the use of the various devices employed in such cases, for I know of many in which the devices could not have been dispensed with, in this particular instance I could see no indication for their employment and therefore I simply used the roller bandage, with a happy result; to have used one of those devices would have been a useless expenditure and cumbrance to my patient.

The points I wish to emphasize in the care of this case are the following:

1. Despite the fact that conditions around railroad shops are rather conducive to infection in wounds of every character, and especially in compound fractures, yet in this case infection did not occur.

2. Not only was there no extraction of a tooth, as recommended by many, but I did not remove the one that was loose.

3. No apparatus of any kind was employed, and at the end of the second week the bandage was discarded and semisolid food masticated, the average case requiring a month.

I admit that this is a distinct departure from the ordinary custom and a considerable risk, but the progress was so unusual that I felt the conditions warranted the trial. It is impossible to obtain a text-book which covers every case, as all of us are willing to acknowledge, and it is in the exceptional case that we have to rely on our own resources.

The spicule of bone is accounted for by the fact that the velocity of the striking force, so to speak, was so high that there was an "explosive effect" and lateral transmission of energy to an extent sufficient to cause this colution of continuity; an example of this is seen in the modern missile. This destructive effect occurs only in certain organs and tissues (such as compact bone or organs containing fluid) because these organs and tissues best transmit the energy imparted by the missile. Had this sledge-hammer been moving at a lower velocity, the shock in the bone would not have been so great, the disruption consequently less, and a complete fracture, without the spicule of bone, would have been the result.

103 North Fourth Street.

Predisposition to Cutaneous Affections After Acute Infectious Diseases.—S. C. Beck has encountered more than 50 cases in which various skin diseases developed in children immediately after some acute infectious disease. This list does not include the numerous instances in which a tuberculous cutaneous affection developed after measles—the peculiar predisposition to tuberculosis left by measles is a fact too familiar for more than passing mention. He also excludes the numerous cases of folliculitis, furunculosis and pyodermitis following typhoid or pneumonia, restricting his study exclusively to the cases in which the skin after an acute infectious disease displayed an exceptional predisposition to the changes produced by toxic substances generated in the intestines, and it also seemed to be changed to a more favorable soil for various bacteria or other noxious influences from without. In 30 of his cases, urticaria, eczema or various rashes developed after vaccination in children free from any such tendencies in the past. He tabulates the details of 51 cases in the *Monatshefte für prakt. Dermatologie*, 1909, xlix, 432.

BETTER ANESTHESIA IN MEDIUM-SIZED HOSPITALS

SOME YEARS OF BROOKLYN EXPERIENCE *

ROBERT L. DICKINSON, M.D.
Gynecologist to Brooklyn Hospital, Obstetrician-in-Chief to Methodist-Episcopal Hospital, Consultant Gynecologist to St. Mary's Hospital, Jamaica.
BROOKLYN

Anesthetically, the hospital field in general, like all Gaul, is divided into three parts.

First come the great institutions which we of the hundred-bed class and two-hundred-bed class regard from afar, ascribing to them unlimited incomes. For them a salaried staff of expert anesthetists is possible, and from them it should be required. Indeed, the public would demand it if the public had any idea of how preposterously ill-balanced the operating-table often is with a resourceful and fearless expert at one end and a scared and clumsy novice at the other.

Next is the small group of private hospitals, which can hardly do better than follow the plan of Baldy and the Mayos, who train an intelligent woman to do that one thing well. Such salaried service is reliable and unvarying. The work is dignified and permanent. Under such conditions it would no longer be considered a makeshift position as it so often is at present by the men of the stop-gap services. Indeed, we may reasonably assume that physicians of moderate ability who have found themselves, in some ways, unsuited for general practice will be glad of a suitable income from such a source.

The third group is by far the largest. The country is covered with hospitals of medium size, in large cities as well as in small towns, where ether is administered in the most haphazard fashion. This is the serious condition which confronts us, and to meet it I am offering the following practical suggestions, as a step toward realizing the development of that perfected anesthesia toward which we have set our faces.

If we must, for the present, ignore ideals impossible to attain, let us see whether we find any hospitals which are able to maintain high standards of ether administration without raising the salary budget. Can it be done? It has been done by offering adequate inducements to men who are qualified, or inducements sufficiently great to cause men to qualify. They may be tendered one at a time, as a man develops, or all at once. These may be: (1) a title, such as "anesthetist to the hospital;" (2) membership on the visiting staff, or assistant visiting staff; (3) privileges, such as (a) use of operating-room for the anesthetist's own cases, or (b) a free bed or free beds; (4) fees for administering anesthetics to private patients whenever the operation fee warrants it; (5) the understanding that the surgeons of the staff will make operations done in private houses contribute toward the income of the anesthetist.

Chosen for fitness, an ex-intern who has shown natural aptitude for the work, or one of the attachés of the surgical staff who will undertake to give a reasonable time to the work, is elected by the professional staff as anesthetist. He appoints an associate or assistant, or more than one, according to the amount of surgical work done in that particular institution.

In this way responsibility is fixed. If patients are drowned in ether, or complications are frequent, or after-distresses prominent we know to whom to go.

---

* Given, in abstract, before the American Gynecological Society, April, 1909.

Duties are defined. Whenever the staff rotates the anesthetist shall train the new house anesthetist or determine whether previous experience has qualified him. In the gravest charity operations always, and in others whenever called on by the operating surgeon, he shall give or supervise the giving of the anesthetic. In private cases, when called on to anesthetize, he may claim a reasonable fee, either in the form of a percentage of the fee or, preferably, as a separate charge. The separate charge adds dignity to the work and attracts a better type of man into it.

As to the period which the incumbent should serve, it is to be specifically understood at the time of appointment that the office is not a narrow stepping-stone, but that the work must be seriously undertaken for a time, such as two or three years. The surgeons do not bind themselves in any way to employ this hospital officer in their operations outside of the hospital. They should, however, extend a reasonable hope that if he will better the anesthesia and lessen the dangers in their charity surgery he will be rewarded by calls to their outside work. Success inside the building will eventually make the anesthetist wanted outside. So the situation takes care of itself, and to the young man an assured sum, even $500 or $1,000 a year, is no small matter. In regard to the length of time that the anesthetist shall give or supervise the anesthetics at the time of rotation of service of the house staff, this will depend on the capabilities and quickness of the particular intern who becomes house anesthetist. When a man is entirely inapt serious cases may have to be watched throughout his house service.

In any consideration of anesthesia we must not lose sight of our three obligations:

1. To furnish to the particular patient the best possible anesthesia.
2. To supply to the general public as many members of the profession as may be who will have a fair working knowledge of the administration of anesthetics. And our duty shall always be, first to the members of the house staff, and, incidentally, to advanced medical students.
3. To train for the profession, and for one's own hospital and for other hospitals, a few expert anesthetists.

The last two duties are in practice not incompatible with the first, for the reason that it is the general experience that a patient used for teaching is better studied by the teacher, and is cared for with more detail, than the less observed "case."[1]

The objections usually met are these:

1. The house staff may protest against the loss of this clinical experience. In actual practice it has been found that the fear of active protest is greatly exaggerated, the training highly appreciated, the nervous apprehension of the beginner quieted, and drudgery turned to intelligent progress, provided always that the right teacher-anesthetist has been selected.
2. The operator objects to the cost. It is all right where the fee is fair, but if a hundred-dollar laparotomy must have a ten-dollar ether fee and a ten-dollar microscopic opinion subtracted, there remains little for the surgery and nothing for the after-care.

The time is coming when the private patient will be regularly asked whether he is willing to pay for an ether giver. The bill will be rendered separately or in a separate item. Meanwhile, until the public is educated and its purse loosened, the subtraction will have to be a small one—say 5 per cent.

3. The work will be considered drudgery.

It is drudgery. So it must either be paid for or the present malpractice continue. The payment will be various—in money, in recognition, in promotion, in praise for improved results, and credit by the publication of these, and in the personal satisfaction in good work, bitterly needed and well done.

168 Clinton Street.

---

[1] Brooklyn has a live society of anesthetists consisting of twenty members having active services and an average attendance of fifteen at its meetings. Anesthetists are officially on the staffs of the following hospitals [illegible] priority of their appointments: Long I[illegible] Williamsburg, Bushwick, Norwegian, Jew[illegible] Methodist Episcopal, Cumberland Street, [illegible]spect Heights.

It would seem, therefore, that the only cities in Europe or America that can claim a systematized practice of anesthesia are London and Brooklyn.

TWO CASES OF PELLAGRA

W. T. SHELL, M.D.
CORSICANA, TEXAS

In view of the increasing prevalence of pellagra, I wish to make a brief report of two cases.

CASE 1.—The patient, a married woman, white, aged 30, had had no serious illness previous to the spring of 1907, when she had an eruption on the side of the neck and backs of her hands. This improved during the summer but recurred in the spring of 1908 and did not disappear as before. In November, 1908, the patient consulted me, complaining of weakness and dyspnea after exertion and of loss of memory. On Dec. 24, 1908, I saw the patient again and found a dermatitis resembling sunburn on the back of both hands and sides of the neck. In the center of this eruption was a reddish, shiny appearance of the skin, the edges having a brownish, dirty look. No other symptoms were noted except increasing loss of strength. A gastritis and enterocolitis soon followed with diarrhea and vomiting. There was lack of feeling in the stomach and bowels. The bowel movements contained blood and mucus. The bladder was completely paralyzed and there was vaginitis. These symptoms grew stedily worse until the patient's death, Jan. 5, 1909.

CASE 2.—This patient was a white woman, married, aged 30. There is nothing of special interest in the family and personal history except that the patient's diet had consisted largely of corn-bread until the last few months, when she could not eat it at all. Digestive disturbances had been present for several months, consisting of constipation, followed by pain in the abdomen and loss of appetite with diarrhea. The eruption appeared on the backs of the hands about January, 1909. The skin on the dorsal surface of both hands was red and shiny. Stomatitis was especially marked and the mucous membrane of the throat very much reddened. There was vaginitis and urethritis, and the skin around the rectum and vagina was inflamed for an inch, beyond which was a roughened scaly eruption. The patient had great pain on defecation. Physical examination of the chest revealed nothing abnormal. With the exception of anemia the blood and urine were normal. Temperature varied from subnormal to 100 F. The inflammation of the skin around the vagina and rectum became pustular, but this cleared up after using a solution of bichlorid of mercury, 1 to 2,000. The patient continued to grow weaker both physically and mentally until her death, Aug. 27, 1909.

Both patients had used a great deal of corn-bread. Further than this the histories throw no light on the etiology.

Greatness.—It is not by birth nor by pedigree but by push that the high places are reached. The men with soft raiment are usually soft all the way through. They are not built for the storms. Greatness is not born under the gambler's roof nor in the inebriate's rendezvous. The manhood of the meadows is mightier than the majesty of the mansions.—*United Presbyterian.*

A CASE OF SPLENIC LEUCEMIA

JOSEPH PLACAK, M.D.
CLEVELAND, OHIO

This case is an interesting one on account of the enormous numbers of leucocytes which were present. The ratio between the white and the red cells, the high percentage of myelocytes, and the excessive number of white cells makes this case one worthy of reporting. Several times during the course of the disease the white cells were 500,000 and over in excess of the red cells.

Patient.—S. B., aged 30, an American woman, white, housewife; family and personal history negative; had had the usual diseases of childhood; mother of two children. She complained of becoming weak, fatigue on the slightest exertion, marked dyspnea, and slight hemorrhages from the mouth. Later the patient was able to feel the enlarged spleen.

Examination.—Development good; nutrition fair; considerable anemia; puffiness of eyelids; slight edema of ankles; glands not generally enlarged; lungs and heart negative but for a hemic murmur.

Left side of the abdomen rounded and prominent. Prominence extended beyond the median line. Mass could be palpated and extended close to the symphysis pubis, smooth with rounded borders. Numerous blood examinations were made over periods of several weeks. Hemoglobin varied from 40 to 25 per cent., increasing for a time on the administration of iron and arsenic. Red cells varied from 1,250,000 to 2,250,000. The interesting feature of the case was the enormous leucocytosis which was attained (1,820,000) and which persisted for a few weeks. Differential counts showed as high as 27 per cent myelocytes.

Shortly before death the axillary, cervical and inguinal glands became enlarged. I have observed this in two other cases of supposedly purely splenic type. No autopsy was obtained.

420 Rose Building.

HEMORRHAGE FROM NIPPLES

L. BUCKLE, M.D.
NEW YORK CITY

M. G., aged 26, iii-para, has enjoyed good health for many years. She had no morning sickness or other illness with present or previous pregnancies. Labor was always comparatively easy and normal. She never had trouble with her breasts.

One week before her present confinement, while massaging the breasts, she noticed some blood ooze from the left nipple. The oozing increased from day to day. There was no pain or tenderness on pressure of breasts. Seven days after she noticed the blood from the left breast she gave birth to a normal child. Oozing from the right nipple was then noticed. At this time both breasts were always wet with blood. The least pressure would increase the flow of blood considerably.

On the sixth day after the birth of the child, no change was noticed in the left breast but the right one showed a few drops of milk after some oozing of the blood. On the following day the oozing from the right breast was no more blood but milk. The left breast, however, kept on bleeding for another week before milk was seen to flow from it.

In the literature at my command I have not been able to find any similar case. Several things may be deduced from this case: 1. There need be no special alarm about bleeding from the breasts at the end of pregnancy or a week or two after the birth of the child. 2. Bleeding from this source is self-limited and does not have any ill effect on the patient. 3. It requires no medical treatment.

321 East Tenth Street.

Therapeutics

DRUGS AND THE UNITED STATES PHARMACOPEIA

While dictionaries, directories and encyclopedias must be arranged alphabetically for ready reference, alphabetical arrangement of drugs for the practicing physician is very unsatisfactory. Also, for a practicing physician, classifications based on chemical constituency, pharmacologic peculiarities, or toxic action are absolutely of no value. A drug may have a chemical, physiologic or toxic activity that if of no value from a therapeutic standpoint.

The classification always of value and always necessary for the practicing physician is one based on therapeutic uses. In other words, for utility, drugs must be classed according to the objects for which they are to be used. For instance: Drugs used to diminish secretion (astringents); drugs used to cause vomiting (emetics); drugs used to dilate the blood-vessels, etc.

Such a classification does not include drugs that may have these activities incidentally or in toxic doses, but the drugs that the physician would use to promote the object desired. Under such headings, the drugs only should be named that accomplish the object desired the most efficiently. It is positively absurd to name under such a classification a lot of useless second-, third- and fourth-rate drugs, or drugs that accomplish the object desired much less efficiently than do drugs of the first rank. It is also manifestly needless, useless and an unnecessary hardship to require medical students to acquire a knowledge of a drug that is rarely, if ever, and perhaps should never be, used in the practice of medicine. It is also just as absurd to require a student to learn a list of preparations of a drug, two-thirds of which are useless or never used, when two or three preparations of that drug, and often only one, are all that should be used therapeutically.

In other words, the United States Pharmacopeia is replete with a lot of useless drugs and preparations so that its usefulness for the practitioner is lessened.

The object of the editorials under this section on this subject is to create sufficient interest among the profession that instructed delegates to the Pharmacopeial Convention of next May, at Washington, will request the Committee on Revision to prepare the Pharmacopeia of 1910 in such form as to be of practical scientific utility.

The following classification, arranged according to therapeutic indications, is copied from Osborne's small text-book on "Materia Medica and Pharmacology."

While it could not be claimed that this enumeration of drugs comprises all that are of value, it does comprise some of the best, and any drug that aspires to a place in such a classification must show positive physiologic activity and therapeutic success to prove that it should be classed among these, the best drugs. Under each heading the drugs are named alphabetically, not because the first drug named is better than the last.

Later, in this department, the best preparations of the drugs in the most important classes will be named. Also, the drugs used for the same objects and official in the present Pharmacopeia, but of second- and third-rate values, will be enumerated and their omission from the next Pharmacopeia urged.

It is probable that, in such an enumeration of drugs of second- and third-rate value, physicians in different parts of the country will be horrified to find a pet drug or preparation condemned. Such an enumeration or condemnation does not declare that a drug is not of value as used by the individual physician, but it simply declares that there are other drugs and preparations that are better. Therefore there is no excuse for continuing a second-rate drug officially in the Pharmacopeia. This is no more radical advice than to declare that there is an improved instrument, bandage, splint or appliance that is better than one that was made and used several years ago. The individual physician or surgeon may still get perfect success out of the old apparatus, but that is no excuse for recommending it as of equal value to the new improved apparatus.

First Division

For Local Action

CLASS 1.—Drugs Used to Destroy Micro-organisms

(a) *To disinfect* (Drugs too strong to be used on the body). For buildings: Formaldehyd, Sulphurous Acid, Steam. For clothing: Formaldehyd, Heat. For dejecta: Chlorinated Lime.

(b) *To inhibit the growth of bacteria on the body or in one of its cavities* (Antiseptics). Alcohol, Cresol, Formaldehyd solution, Hydrogen Dioxid solution, Mercuric Chlorid, Phenol, Salicylic Acid.

(c) *To destroy skin-parasites* (Parasiticides). Beta-naphthol, Chrysarobin, Ichthyol, Iodin, Mercury, Pyrogallol, Resorcin, Sulphur, the above Antiseptics.

CLASS 2.—Drugs Used on the Skin

(a) *To protect* (Dressings). Acetanilid, Bismuth preparations, Boric Acid, Iodin synthetic powders, Lycopodium, Talcum, Zinc Oxid, Zinc Stearate.

(b) *To soothe* (Emollients). Almond Oil, Boroglycerid, Cacao Butter, Glycerin, Olive Oil, Petroleum Oils, Wool Fat.

(c) *To cause hyperemia* (Mild counter-irritation). Tincture of Iodin, Liniments, Mustard.

(d) *To blister.* Cantharides.

(e) *To corrode* (Escharotics). Chromic Acid, Glacial Acetic Acid, Nitric Acid, Potassium Hydrate, Salicylic Acid, Silver Nitrate, Trichloracetic Acid.

CLASS 3.—Drugs Used to Act on Mucous Membranes

(a) *To soothe* (Demulcents). Albumin water, Barley water, Flaxseed infusion, Milk, Warm Physiologic Saline solution, Slippery Elm infusion.

(b) *To diminish secretion* (Astringents). Alum, Bismuth Salts, Weak Silver solutions, Suprarenal preparations, Tannic Acid, Weak Zinc solutions.

(c) *To stimulate.* Copper Salts, Silver Salts, Zinc Salts.

CLASS 4.—Drugs Used for Local Action in the Stomach

(a) *To increase the appetite* (Stomachics). Cinchona, Gentian, Nux Vomica, Salicin, Vegetable Bitters.

(b) *To aid digestion.* Diastase, Hydrochloric Acid, Pancreatin, Pepsin.

(c) *To reduce acidity* (Antacids). Ammonia, Chalk, Lime Water, Magnesia, Sodium Bicarbonate.

(d) *To cause vomiting* (Emetics). Apomorphin (acting on the vomiting center), Copper Sulphate, Ipecac, Mustard, Zinc Sulphate.

CLASS 5.—Drugs Used for Local Action in the Intestinal Canal

(a) *To increase peristalsis* (Carminatives). Anise, Capsicum, Cardamom, Cinnamon, Peppermint.

(b) *To promote evacuation of the bowels.*

Laxatives	*Purges*	*Salines*	*Irritants*
Aloes	Calomel	Magnesium Citrate	Colocynth
Euonymus	Castor Oil		Croton Oil
Magnesia	Comp. Cathartic Pill	Magnesium Sulphate	Elaterium
Podophyllum	Large dose of any laxative	Potas. and Sod. Tartrate	Jalap.
Rhamnus Pursh.		Seidlitz Powder	
Rhubarb		Sodium Phosphate.	
Senna		Sodium Sulphate.	
Sulphur			

(c) *To correct fermentation.* Beta-naphthol, Thymol, Salicylic Acid, Phenyl Salycilate (Salol).

(d) *To remove Parasites* (Anthelmintics). Aspidium, Beta-naphthol, Pepo, Quassia, Spigelia, Thymol.

Second Division

For Systemic Action

CLASS 1.—Drugs Used to Act on the Skin After Absorption

(a) *To stimulate.* Arsenic, Thyroid.

(b) *To decrease perspiration.* Atropin, Sulphuric Acid.

(c) *To increase perspiration* (Diaphoretics). Alcohol, Antipyrin, Pilocarpin.

CLASS 2.—Drugs Used to Act on the Genitourinary System

(a) *To increase the amount of urine.* Buchu, Caffein, Digitalis, Scoparius, Squill, Water.

(b) *To modify the character of the urine.* Hexamethylenamin, Methylene Blue, Potassium Acetate, Potassium Bicarbonate, Potassium Citrate, Salicylic Acid, Salol.

(c) *To stimulate the mucous membranes.* Cantharides, Copaiba, Cubebs, Oil of Santal.

(d) *To increase menstruation* (Emmenagogues). Iron, Manganese Dioxid, Thyroid.

(e) *To contract the uterus* (Oxytocics). Ergot, Hydrastis, Quinin, Viburnum.

CLASS 3.—Drugs Used to Act on the Respiratory Tract

(a) *To increase the secretion of mucous membranes.* (Expectorants). Ammonium Chlorid (small doses), Ipecacuanha, Iodids.

(b) *To decrease the secretion of the mucous membranes.* Ammonium Chlorid (large doses), Atropin, Codein, Heroin, Morphin, Terpin Hydrate.

(c) *To relax spasm.* Atropin, Bromids, Chloral, Gelsemium, Morphin, Nitroglycerin, Stramonium, Tobacco.

CLASS 4.—Drugs Used to Act on the Circulation

(a) *To stimulate the heart.* Alcohol, Ammonia, Camphor.

(b) *To depress the heart.* Aconite, Veratrum.

(c) *To strengthen the heart.* Caffein, Digitalis, Strophanthus, Strychnin.

(d) *To contract the blood-vessels.* Atropin, Ergot, Suprarenal.

(e) *To dilate the blood-vessels.* Nitrites.

CLASS 5.—Drugs Used to Act on the Nervous System

(a) *To stimulate* (Cerebral Stimulants, Antispasmodics, Excitomotors). Asafetida, Caffein, Camphor, Cannabis Indica, Phosphorus, Strychnin, Thyroid, Valerian.

(b) *To depress* (Analgesics; Depresso-motors). Acetanilid, Aconite, Antipyrin, Belladonna, Bromids, Chloral, Lobelia, Opium, Phenacetin.

(c) *To produce sleep* (Hypnotics). Bromids, Chloral, Hyoscine, Paraldehyd, Sulphonal, Trional, Veronal.

(e) *To produce anesthesia.* General: Chloroform, Ether, Nitrous Oxid. Local: Cocain, Ethyl Chlorid, Ice, Menthol, Phenol.

CLASS 6.—Drugs Used to Lower the Temperature of the Body

(Antipyretics). Acetanilid, Antipyrin, Cold, Phenacetin.

CLASS 7.—Drugs Used for Actions Which are Specific

Antitoxin in Diphtheria.
Cinchona in Malaria.
Colchicum in Acute Gout.
Iodids in some disturbances of Metabolism, notably Sclerosis (in small doses long continued).
Iron in Anemia.
Mercury in Syphilis.
Salicylic Acid in Acute Arthritis.
Thyroid in Myxedema.

CLASS 8.—Unclassified Organic Extracts

Mammary.
Ovarian.
Pancreas.
Parotid.
Pituitary.
Testicular.
Thymus.

OPTIC NEURITIS AND TUMORS OF THE BRAIN

Ophthalmoscopy has become a routine procedure in neurologic examinations, and the information thus gathered has been of inestimable service in the diagnosis and therapeutics of nervous diseases in general. In the solution of the special problem of tumors of the brain, however, ophthalmoscopic examination has been less serviceable; while it has indicated the presence, it has done little to establish the localization or the type of such neoplasms.

If ophthalmoscopy was to furnish this much-desired information, thorough, comprehensive study was necessary of the ophthalmoscopic pictures and their relation to the character, location, and size of the new growth within the cranial vault; and fortunately such study has been made. In a comparatively recent paper[1] Leslie Paton has presented a most thorough and interesting analysis of about four hundred cases of brain tumor from the records of the National Hospital for Paralyzed and Epileptic in London. A feature which gives special value to this study is that all of the brains were examined either post-mortem or in the living body in the course of surgical procedures which permitted adequate observation.

Passing over many technical points, which cannot be adequately reviewed here, three groups of facts are worthy of comment: that is, those dealing with the incidence and severity of the optic neuritis, with the location of the tumor, and with the eye changes—points of paramount importance to the ophthalmologist, neurologist, and psychiatrist.

Paton is far from dogmatic in his assertions, but regarding incidence of the optic neuritis he reaches the following conclusions:

1. When a tumor, directly or indirectly, exercises constant pressure on the chiasm or on the optic nerves, it is likely to cause a primary atrophy without any preceding edema of the disc.

2. The absence of optic atrophy is not infrequently indicative of meningeal tumors without involvement of the brain substance.

3. There are two regions of the brain, the pons Varolii and the white matter of the cerebral hemispheres, in which tumors frequently develop without causing optic neuritis.

Concerning the severity of the neuritis, the amount of retinal swelling, as measured by the height, the turgescence, and capillary congestion, offers a fairly reliable guide; so do hemorrhages and dusky, yellowish patches of exudate. An equally important element in the picture is the extent to which the neighboring retina is affected by the spreading of the edema from the neighborhood of the disc. In certain very severe cases a macular fan shows a spreading edema. This is evidence of a neuritis of gross character, and never appears with the lower degree of swelling. Loss of sight is a very unsatisfactory indication of the severity of the neuritis.

Some of the most interesting facts that may be gathered from this extensive paper concern location, and the conclusions drawn therefrom furnish almost the only general guides in this difficult field. Precentral tumors, Paton says, are nearly always associated with a fairly severe neuritis, whereas postcentral tumors are nearly always associated with a neuritis which is as a rule moderate and often of very short duration.

A neuritis of severe grade is found, moreover, with tumors of the optic thalamus and midbrain, while cerebellar and extracerebellar tumors of the posterior fossa cause a neuritis of a grave character, but apparently less severe than the preceding.

Temporosphenoidal tumors are almost invariably associated with a neuritis as grave as precentral or frontal tumors, while subcortical tumors develop a neuritis in only about 50 per cent. of the cases and this, when present, is as a rule mild and, with parietal tumors particularly, of short duration.

In practically one-half of the cases a difference in severity of the neuritis in the two eyes may be noted, sometimes being greater on the side of the tumor, at other times on the opposite side. This difference, then, is an untrustworthy sign and should be disregarded. The pathologic nature of the tumor does not in itself play any part in determining the onset of the neuritis, except in so far as the nature of the tumor determines its location. The age of the patient in itself bears little or no relation to the occurrence of neuritis.

This contribution of Leslie Paton's will undoubtedly give some assistance in the difficult task of the localization of cerebral neoplasms and should serve to emphasize the desirability of more searching ophthalmoscopic examinations on the part of both nerve and eye specialists.

THE EPIDEMIOLOGY OF TYPHOID FEVER

It is but little more than half a century since typhoid fever became first recognized as a disease different from other "slow" or "continued" fevers or even distinct from typhus fever. And yet in few other diseases has greater progress been made toward definite conceptions of cause, mode of spread and manner of prevention.

---

[1] Paton, Leslie: Brain, 1909, xxxii, No. 125.

The realization of the part played by contaminated drinking-water came very early in the study of modes of dissemination of this infection. It is natural that this should have been the case in view of the explosive character and frequent striking localization of water-borne outbreaks. Epidemics like those at Plymouth, Ithaca and Butler in this country tend to focus attention on drinking-water as a primary source of infection. The practice of distributing to the inhabitants of cities raw drinking-water mixed with sewage is, however, steadily receding. It is not necessary to recapitulate here the various procedures by which improvement of public water-supplies has been brought about. Although much still remains to be done, especially in the United States, it cannot be questioned that the reduction in the amount of water-borne typhoid in the last twenty-five years in all civilized communities has been enormous.

As often happens in infectious diseases, the steady diminution of typhoid cases due to one cause has brought into prominence other factors previously unnoticed or regarded as of little significance. Sanitary authorities everywhere have found that the complete eradication of typhoid fever, a typical "preventable" disease, is one of the most difficult of public health problems. It has happened more than once that after a community has obtained a pure and uncontaminated water-supply the typhoid mortality has remained excessively high. The experience of the city of Washington, D. C., affords a well-known illustration of the subordinate rôle that may be played by drinking-water in causing typhoid in a great city. The typhoid fever that still occurs in a community after the public water-supply has been effectively purified has sometimes been designated as "residual" typhoid, but the term seems to be an unfortunate one so far as it implies that the major source of infection has been removed by the elimination of infected water. For it must be admitted that in a great many communities, in this country and in Europe, drinking-water is at the present time a subordinate factor in the causation of typhoid fever. It seems necessary to emphasize this fact, since exaggerated statements have sometimes found utterance; such, for example, as the view expressed by a well-known sanitary engineer to the effect that the universal purification of water-supplies would do away altogether with typhoid fever, or the popular saying, apparently based on the assumption of official negligence in the matter of water-supply supervision, that "for every case of typhoid fever some one should be shot." Naive expressions of this sort can do only harm. It would be well if the general public realized more keenly some of the difficulties in the way of the complete suppression of typhoid fever.

These difficulties have been made apparent to some extent by the investigations of typhoid fever in Washington, published by Rosenau and his associates, and they are again brought to light in Kayser's study of this disease in Strasburg.[1]

From Kayser's observations, which extend over more than three years, it appears that raw milk is credited with causing in all probability 26.7 per cent. of the cases, while only 14.6 per cent. could be traced to water infection (including infection while bathing). Contact with typhoid patients—mostly atypical cases—was apparently responsible for 16.8 per cent. of the cases, while as many as 9.5 per cent. were found to be due to the agency of typhoid carriers! Other less important sources of infection were discovered, such as the consumption of infected food substances and contact with infected clothing or with the contents of privy vaults. In about 13 per cent. of the cases, the disease seemed to have been contracted outside the city. In all, about 87 per cent. of the typhoid cases in Strasburg could be traced to a plausible origin. Kayser seems inclined to attribute the 13 per cent. of unknown origin in large part to the agency of unrecognized typhoid carriers; and certainly the facts in the body of his paper countenance this view. It may be noted that this experienced investigator apparently does not attach so much importance to insect carriers as do many recent American writers.

Among the noteworthy points brought out in the Strasburg investigation is the existence of "typhoid streets" or localized areas in which the disease is disproportionately prevalent. A remarkable liability on the part of certain occupations is likewise observed. Not only is the mortality among professional nurses very high, but the number of cases occurring in persons having to do with the handling and preparation of food substances is amazingly great. Bakers, cooks and milk dealers all have a much higher mortality (1.1 per cent.) in proportion to the numerical strength of their respective occupations than agricultural workers (0.12 per cent.) or employees in paper or textile factories (0.0 per cent.). As Kayser says, in Strasburg typhoid fever can almost be considered as an occupational disease.

Kayser's investigations do not tend to minimize the importance of the bacillus-carrier as an agency in spreading typhoid. Of the twenty-eight known carriers in Strasburg, eleven were definitely implicated in the causation of new cases and nine of the others were with less certainty under suspicion of having disseminated the infection. The difficulties in the way of placing restraint on the occupational freedom of known typhoid carriers are strongly set forth in Kayser's paper. There can be no doubt that control of the sources of infection in typhoid fever offers a serious problem to the public health administration.

---

TRAMMELING THE SANITARY DEPARTMENT OF THE CANAL ZONE.

The work of the Department of Sanitation in the construction of the Isthmian Canal has been closely observed by sanitarians all over the civilized world. In fighting disease, much depends on the accuracy of the information and the promptness with which it is received. Frequent communications between boards of health are as necessary as weather bulletins. The progress of an epidemic, the discovery of new methods of overcoming disease, if transmitted at once to other health officers, may mean the saving of thousands of lives. Frequently issued and widely distributed sanitary bulletins are of the greatest value. Most of the states and a large number of cities issue monthly health reports. The United States government maintains in Manila a sanitary department for the control of diseases in the Philippine Islands which publishes health reports regularly. The United States Public Health and Marine-Hospital Service also publishes weekly reports. All of this matter is carefully scanned by modern health officers and thus the knowledge and experience of one is of assistance to all.

One of the most important things done by Colonel Gorgas, chief sanitary officer of the Canal Zone, was the monthly publication and distribution of the Report of the Department of Sanitation of the Isthmian Canal Commission, which was eagerly looked for and carefully read by all officers of health, not only for information regarding the suppression of disease in the Canal Zone, but also for valuable data on general sanitation and the control of diseases, especially in the tropics. This monthly pamphlet was regarded by sanitarians everywhere as of the greatest value and among the most important of the publications on tropical diseases. It was also of great value to the Department of Sanitation itself, for it brought to it, through exchange, similar publications from other workers, at home and abroad.

It was, therefore, with surprise and regret that sanitarians learned that in March, 1909, the publication of these reports was discontinued by order of Lieutenant-Colonel George W. Goethals, the army engineer officer in charge of the construction of the canal, who evidently did not know that the results obtained by the Department of Sanitation were of interest either to the public or to the medical profession.

In reply to a letter sent from The Journal, asking why the reports were no longer sent out, the Isthmian Canal Commission stated that the printing of these reports had been discontinued, but that "brief synopses of the reports of the Department of Sanitation have appeared in the monthly reports of the chairman of the commission, which have been published regularly in the *Canal Record.*" Examination of seven consecutive numbers of the *Record,* running from June 30 to Aug. 11, 1909, shows that many pages have been devoted to reports from the engineering and construction departments and that much space has been taken up by the monthly record of the performance of steam shovels, building construction, record of excavation, tables showing the height of the tide, amount of rainfall, the exact height of the Chagres River, the rebuilding of the Panama Railroad, the classification of accounts, the awards of contracts, wage classification of employees, and even the social doings on the Isthmus, including clubs, lectures, dances, bowling and indoor baseball, but that less than one column in the seven numbers has been devoted to the work of the Department of Sanitation. Yet even in this small space the surprising record made by the department is evident, since the report shows that the death-rate in the Canal Zone has been reduced from 50.57 per thousand in June, 1905, to 16.42 per thousand in June, 1909, and that, although there were 97 deaths in June, 1906, when the employees numbered only 28,010, there were in June, 1909, only 37 deaths, 60 less than in June, 1906, although the number of employees had increased to 47,493. And yet the Canal Commission considers these facts, showing one of the most brilliant sanitary records ever made, of no interest to the public and of little or no importance to sanitarians.

The work done by Colonel Gorgas in the Canal Zone has been a most striking object-lesson to the people of the United States as to the ability of modern sanitary methods to control disease. It has also had a valuable educational effect on the American public. It is highly probable that if the Department of Sanitation had not made the showing which it has in the suppression of disease, and if it had not sent its reports broadcast, the Canal Commission would now have great difficulty in securing employees. The influence of these monthly reports on health conditions in neighboring Central American states is by no means to be underestimated. Yet their publication and distribution are forbidden on the grounds of economy, when their actual cost to the government is less than $200 a month. What would be thought of a chief sanitary officer if he assumed to veto the plans of the directing engineer for bridges, tunnels, and grades in the railroad work in the Canal Zone? How much importance would the American public attach to the opinions of a medical officer on the strength or position of dams and locks or the construction of steam shovels used in canal construction? Yet this is no more ridiculous than for an engineering officer to attempt to dictate to the Department of Sanitation as to technical details in sanitary matters. The work done by the Department of Sanitation is of vital importance to the completion of the canal, and the American people, when they fully understand the situation, will not only demand that the chief sanitary officer of the Isthmus be allowed to continue his work untrammeled, but that the widest publicity be given to the results obtained in his department in order that all diseases, and especially those peculiar to the tropics, may be further controlled and, if possible, eliminated.

THE VINDICATION OF GALL

Most physicians know the name of Gall because they have heard of the columns of Gall and Burdach in the spinal cord; but few realize that the Dr. Gall who is thus commemorated is the father of so-called phrenology—that is, the attempt to determine intellectual capacity and mental characteristics from the appearance of the skull—and also the pioneer discoverer of the physiology of the brain. Dr. Bernard Hollander, who is president of the Ethnological Society and physician to the British Hospital for Mental Disorders, has spent many years in vindicating the reputation of this great anatomist of the brain from undeserved aspersions and from exaggerated pretensions made by disciples.[1] Gall's career illustrates the penalties of being before one's time in knowledge. It is dangerous to discover, before men's minds are prepared for the truth, the circulation of the blood, or that the heart is a muscle, or that the earth moves, because, as Harvey and Steno and Galileo realized to their cost, men do not like to have their cherished beliefs turned to foolishness.

At the end of the eighteenth and the beginning of the nineteenth century four men in Paris startled the scientific world, gained a momentary celebrity, and then lapsed into oblivion. They were Cagliostro, Lavater, Mesmer and Gall. A good idea of Cagliostro's character may be obtained from Dumas' "Memoirs of a Physician." Lavater did good work in physiognomy, as any one who goes back to his books will readily appreciate, but he utterly exaggerated the significance of his observations. What Mesmer exploited under the name of "animal magnetism" has been used by quacks ever since, under one name or another; but it must not be forgotten that what he did forms an important chapter in the history of psychotherapy. Cagliostro, Lavater and Mesmer had more of the charlatan than of the scientist in them. The fourth, Francis Joseph Gall, undoubtedly made the best investigations on the brain that had been made up to his time, but because what he discovered was contrary to popular belief his work came to be ranked with that of the charlatans.

Now comes the vindication of Gall. Several discoveries in the anatomy of the nerves undoubtedly belong to him. He was the first to show that the gray matter precedes the white in origin and in importance; he traced the origin of the nerve bundles from the gray matter and taught that the gray substance nourished the white fibers. He traced the origins of the olfactory, the oculomotor, the trigeminal and the abducens nerves. He established the certainty of the decussation of the pyramids, when such men as Bichât, Magendie, Morgagni and Prochaska were opposed to it. Above all, he was the first to describe the formation and development of the brain in the fetus and to call attention to the simplicity of the convolutions in new-born infants and in idiots, as compared with the complexity of the brain of the normal adult. Many of these discoveries are usually referred to other anatomists. A typical example of a wrong done to Gall is the naming of the island of Reil, which Gall had described long before, after another anatomist of his time, who had been present at some of Gall's demonstrations. These discoveries of Gall are now generally acknowledged.

The reason Gall did not receive recognition during his lifetime apparently was that Napoleon in some way acquired a prejudice against him; hence it became fashionable to disparage Gall. Before this some of his contemporaries had been most enthusiastic in their praise of his work. Flourens, whose own observations on the brain made at this time are of so much value, declared: "I shall never forget the impression I received the first time I saw Gall dissect a brain. It seemed to me as if I had never seen this organ." Geoffroy St. Hilaire, the famous French naturalist, who tried, before Napoleon's displeasure was known, to obtain Gall's election to the French Academy, wrote: "I shall always remember our astonishment, our sensations, our enthusiasm, on seeing Gall for the first time demonstrate his anatomic discoveries. The word 'brain' will always call up to mind the name of Gall." For many years Gall lived in obscurity. Toward the end of his life some slight honor for all his work came to him. His monument in Père Lachaise, where he lies buried, has recently been renovated; and now it would seem that at last his merits are to receive the appreciation that they so richly deserve.

THE PRESIDENT'S MESSAGE AND THE PROPOSED NATIONAL BUREAU OF HEALTH

The movement originally instigated and long fostered by the medical profession for more comprehensive national health service has received a distinct impetus from President Taft in his message laid before Congress on Tuesday of this week. The part of his message relating to this subject is as follows:

"For a very considerable period a movement has been gathering strength, especially among the members of the medical profession, in favor of a concentration of the instruments of the national government which have to do with the promotion of public health. In the nature of things, the Medical Department of the Army and the Medical Department of the Navy must be kept separate. But there seems to be no reason why all the other bureaus and offices in the general government which have to do with the public health or subjects akin thereto should not be united in a bureau to be called the 'Bureau of Public Health.' This would necessitate the transfer of the Public Health and Marine-Hospital Service to such a bureau. I am aware that there is a wide field in respect to the public health committed to the States in which the Federal Government cannot exercise jurisdiction, but we have seen in the Department of Agriculture the expansion into widest usefulness of a department giving attention to agriculture when the subject is plainly one over which the states properly exercise direct jurisdiction. The opportunities offered for useful research and the spread of useful information in regard to the cultivation of the soil and the breeding of stock and the solution of many of the intricate problems in progressive agriculture have demonstrated the wisdom of establishing that department. Similar reasons, of equal force, can be given for the establishment of a bureau of health that shall not only exercise the police jurisdiction of the Federal Government respecting quarantine, but which shall also afford opportunity for investigation and research by competent experts into questions of health affecting the whole country or important sections thereof; questions which, in the absence of federal governmental work, are not likely to be promptly solved."

---

[1] Hollander, Bernard: The Unknown Life and Works of Dr. Francis Joseph Gall. An Inaugural Address delivered before the Gall Society on May 15, 1909. Paper. Pp. 31. Price, one shilling. Published for the Gall Society by Siegle, Hill & Co., 2, Langham Place, London, W.

This subject has been discussed by President Taft from the viewpoint of both the jurist and the practical statesman. Addressing himself primarily to the constitutional question involved, he has anticipated the argument that has perennially been brought forward by the enemies of every measure that contemplated the control by the national government of interests susceptible of concurrent control by the states. This argument was urged long and successfully against the organization of both the Department of Agriculture and the Department of Commerce and Labor, but in both instances a broader and wiser interpretation of the Constitution prevailed. No cry of "special legislation" can be raised against a national public health bureau, since no class or social group will be the special beneficiary of such a step. This was recognized a few years ago, when, in the presence of an invasion of yellow fever, the governors of the southern states, in formal conference, yielded certain prerogatives in sanitation to the Federal Government. This action, from those who had jealously guarded the rights of their states, was a forceful recognition of the fact that sanitary regulation for the general welfare ought to be a function of the general government. If a constitutional way can be found for the federal control of yellow fever, why may it not be found for the federal control of tuberculosis, cancer and typhoid? It would seem that the President is disposed to go as far in this direction as his acute and professional intimacy with the Constitution will permit.

The recommendation of President Taft may be a disappointment to those who feel that our national health interests require a separate department with a secretary. It is, however, one thing to wish for a thing and quite another to get it, either for the President or the people, since both must recognize that an evolutionary process has been established through which administrative agencies must pass. A bureau of agriculture, for instance, with a commissioner in charge, was established in 1862, but did not become a department until 1889. A bureau of labor and other bureaus, each in charge of a commissioner, preceded the organization of a Department of Commerce and Labor. If President Taft's policy can be carried out and if the health service can be placed on a basis of uniformity of organization with other services of the government, we may confidently look forward to its speedy development in prestige, power and usefulness.

THE VIABILITY OF THE TUBERCLE BACILLUS

There has been a good deal of discussion and considerable diversity of opinion as to the length of time the tubercle bacillus may survive extrusion from the animal body. The matter is of no little importance, as on a decision of the question must depend the application of certain measures of prevention. At first it was believed that the tubercle bacillus contained spores and that it was correspondingly resistant to various destructive influences. It was eventually found, however, that the apparent spores were due to beading of the organism in consequence of changes in the protective waxy covering by which its body is surrounded. Recent investigation, moreover, seems to show that the tubercle bacillus has no greater resistance to such agencies as heat, drying, chemicals, sunlight, than most other non-spore-bearing bacteria. Rosenau[1] has shown that exposure to a temperature of sixty degrees Centigrade for twenty minutes is sufficient to destroy tubercle bacilli in milk, bouillon, water and other fluids. In sputum, in dust, in water and on fabrics, on the other hand, the organism may survive for months, although probably the larger number soon die. In pure culture, however, the tubercle bacillus lives for only a comparatively short time, even under the most favorable conditions; and it is generally agreed that the organism succumbs within a few hours to the action of direct sunlight.

As a result of his own observations and of a comparison of his work with that of others Rosenau[2] arrives at the conclusion that there is no easy method of determining the death of the tubercle bacillus. The virulence of the micro-organism vanishes before death takes place. The latter can be determined only by animal experimentation. Dead tubercle bacilli cause lesions indistinguishable from those due to living bacilli, and many erroneous conclusions have been reached from lack of appreciation of this fact.

THE RED CROSS CHRISTMAS STAMP

The sale of Red Cross Christmas stamps, which was so successful last year and is being repeated this year, has several admirable features. Of course, the humanitarian purpose of the enterprise—the raising of funds with which to carry on the campaign against tuberculosis—cannot fail to receive the hearty approval of physicians and laymen alike. These stamps, moreover, which invite the pennies of children and the nickels and dimes of persons with limited means, must create an interest in the work which only a sense of cooperation can give. No imposing subscription list, headed by the names of millionaires, could enlist the active sympathy of the people as can this opportunity for the youngest and the poorest to make their modest offering, secure that it will not be despised. The wide-spread use of the attractive little stamp[1] with its Christmas message must in itself be an educating influence in the antituberculosis crusade. The work deserves the cordial support of all, and physicians especially must desire its success.

Medical News

ARKANSAS

New Board of Health.—Drs. Edward P. McGehee, Lake Village, J. T. Blanks, Dermott, and James W. Nicholls, Readland, have been appointed members of the board of health of Chicot county.

Damage Suit Dismissed.—The suit of Dr. Thomas B. Rider, Hot Springs, for $20,000 damages against Dr. Gilbert C. Greenway and other physicians prominent in the Visitors' Protective League, is said to have been decided against the plaintiff, November 20.

Sanatorium to be Built.—The Arkansas Tuberculosis Commission has made arrangements to proceed with the erection of a state tuberculosis sanatorium, which is to cost $50,000. The site, which was donated to the board, is three miles from Booneville and contains a thousand acres.

Elections.—The Third District Medical Society held its annual meeting in Lonoke recently and elected Dr. Henry Rightor, Helena, president; Dr. Thomas J. Stout, Brinkley, secretary, and Dr. Eugene A. Callahan, Carlisle, treasurer.——The physicians of Polk county met at Russellville, November 4, and organized the Polk County Medical Association, electing Dr. Robert M. Drummond, Russellville, president, and Dr. Roy W. Darr, Atkins, secretary-treasurer.

ALABAMA

Asks Physician to Collect Data.—Dr. W. H. Sanders, Montgomery, state health officer, has issued a circular letter to the physicians of the state, urging them to do their full duty in the collection of data of diseases and reports of same. He lays especial stress on the prevalence of pellagra and asks that careful statistics be collected.

New Society Formed.—The Birmingham Surgical and Gynecological Society has been organized with thirteen charter members, and has elected the following officers: President, Dr. Benjamin G. Copeland; vice-president, Dr. Gaston Torrance; secretary-treasurer, Dr. Edward P. Solomon, and executive council, Drs. John D. S. Davis, William M. Jordan, and Lewis C. Morris.

Mobile Physicians Protest.—Fifty physicians of Mobile city and county have signed a petition protesting against the unwarranted restrictions imposed by the prohibition laws of the state and further protesting against such restrictions by the passing of the proposed constitutional amendment. The law referred to prohibits the sale of alcoholic spirits on physician's prescription or otherwise. All hospitals and infirmaries are prohibited from using alcoholic stimulants.

CALIFORNIA

Gives Ambulance to Hospital.—A Studebaker hospital ambulance, fully equipped, has been presented to the San Mateo Red Cross Hospital by Mrs. M. J. O'Connor.

Warning.—The readers of THE JOURNAL are warned against a person calling himself "Dr. A. Cato," and pretending to sell goods from the Victor Electric Co., of Chicago, on commission. His method of procedure is said to be to sell a bill of goods, get part payment in cash, and then not to deliver the goods.

September Births and Deaths.—During September, there were reported 2,710 births, equivalent to an annual birth rate of 16.2 per cent. per 1,000. During the month 2,353 deaths were reported, equivalent to an annual death rate of 14 per 1,000. Of these 370, or 15.7 per cent., were due to diseases of the circulatory system and 327, or 13.9 per cent., to tuberculosis of various forms.

Sanatoria.—The managers of the Colfax School for Tuberculosis have enlarged their facilities by the purchase of the Tokayano Ranch of sixty-five acres near the town and will proceed at once to erect twenty cottages, and more as required. Dr. Robert A. Peers is medical superintendent of the institution.——Dr. George H. Juilly, San Francisco, is equipping a building in San Mateo for a sanitarium.

Tropical Diseases and Parasitology.—A course of lectures in tropical medicine and medical parasitology will be given in the Oakland College of Medicine, beginning January 3, and lasting for twelve weeks, under the direction of Dr. Creighton Wellman. Two lectures and laboratory demonstrations will be given each week, and interesting tropical cases at the school and various hospitals will be exhibited and studied.

Physicians Injured.—Dr. M. S. da Silva, Sacramento, was seriously injured November 18, when a street car crushed his buggy against a pile of lumber, throwing him out and causing severe contusions.——Dr. Charles S. Taylor, Los Angeles, was seriously injured in San Francisco, October 23. He was standing on a street car when a buggy collided with the car and one of the shafts was forced into the doctor's right thigh for three inches.

Personal.—Dr. Raymond Russ, Sacramento, has been appointed medical inspector of the state board of health.——Dr. Wallace I. Terry, San Francisco, retiring chief surgeon of the Emergency Hospital, was given a banquet by the assistant surgeons of the staff, October 29, over which Dr. Charles B. Pinkham, the new chief surgeon, presided as toastmaster.——Dr. Stewart McL. Doherty, first assistant physician at the Napa State Hospital, is said to have been dismissed by the board of managers, November 18.——Dr. Robert A. Peers, Colfax, has retired from general practice and will devote himself entirely to the care of tuberculosis. Dr. Henry T. Rooney, San Francisco, will take charge of the general work at Colfax.——Dr. John U. Force has been appointed health officer at Berkeley, vice Dr. Julian J. Benton.——Dr. Martin H. Fischer, professor of pathology in the Oakland College of Medicine, has been awarded the Nathan Lewis Hatfield prize of $500 for original research work in medicine.——Dr. Lionel S. Schmitt, San Francisco, has resigned from the U. S. P. H. and M.-H. Service, and will resume private practice. The attaches of the health department, on October 30, presented Dr. Schmitt with a silver and bronze desk set.

Hospital Interests.—The cornerstone of the new San Francisco County Hospital was laid November 20, under the auspices of the board of health, Dr. William Ophuls, president of the board of health, acting as chairman. The buildings are to cost $2,000,000, and will include a general hospital, an isolation hospital, a tuberculosis hospital, and all necessary buildings for power plant, laundry, morgue, ambulance sheds, and stables.——Plans for a new three-story fireproof hospital for Alameda county have been formulated by a committee consisting of Drs. Daniel Crosby, Fruitvale; Oliver D. Hamlin, Oakland; and William A. Clark, San Leandro.——The old wing of the recently rebuilt St. Luke's Hospital, San Francisco, was destroyed by fire November 18. Twenty patients were removed from the hospital without casualty. Plans have been prepared by the directors of the hospital for the restoration of the institution to its original scope and efficiency.——San Jose is soon to have two new hospitals. A contract has been awarded for the erection of the Contagious Disease Hospital, near the O'Connor Hospital, to cost $9,000, and the Bird Haven Company has let the contract for the erection of a sanitarium for nervous diseases, to cost $5,000.——The Northern California Hospital, Eureka, has recently been completed at an expense of more than $80,000, and is now open and in charge of Drs. Charles C. and Curtis O. Falk.——The contract for the erection of the new St. Francis Hospital, San Francisco, has been awarded for $154,500 for the structural work alone. The new building will cover a space 103x137½ feet, is to be five stories and basement in height, and of steel and reenforced concrete construction.——Fabiola Hospital, Oakland, was benefited to the extent of more than $3,000 by the benefit performance November 2.——The Peninsula Hospital, Palo Alto, will be opened this month. The exterior of the building is completed and as soon as the equipment is received, the institution will be ready to open.

COLORADO

Library Transferred.—The medical library of the Denver Academy of Medicine has been transferred to the Medical Society of the City and County of Denver.

Personal.—Dr. Albert L. Bennett, Denver, has been appointed local consul for Japan.——Dr. Henry S. Denison, Denver, has been appointed editor of *Colorado Medicine.*——Dr. Donald

---

[1] Described in THE JOURNAL A. M. A., Oct. 30, 1909, liii, 1495.

Gregg, Colorado Springs, has been appointed resident physician of the new government hospital, Manila, P. I.——Dr. George W. Morse, first assistant physician of the Modern Woodmen Sanatorium, Colorado Springs, has resigned and will return to Denver.

The Tuberculosis Fight.—A society woman of Colorado Springs has placed $10,000 in trust, the income of which is to be used in caring for poor patients suffering from tuberculosis. Dr. Charles F. Gardiner has been made almoner of the fund. A second fund of $10,000 has also been placed in trust for the benefit of destitute sufferers from tuberculosis.——About $3,000 of the $10,000 required to build the Associated Charities Sanatorium in Colorado Springs has been pledged.

CONNECTICUT

Sanatorium Site Purchased.—At a meeting of the State Tuberculosis Commission, November 23, a tract of about thirty acres of land on Cedar Mountain, near Hartford, was decided on for the Hartford county sanatorium.

Physicians Offer Services.—The physicians of Manchester have signed an agreement providing for free service to dependent poor of the town, "when deemed proper," and approving of the appointment of a town physician.

Epileptic Colony.—At the last session of the legislature, a bill was passed providing for the establishment of a colony for epileptics, for an appropriation of $25,000 for the purchase of a site, and for the appointment of a commission to select and purchase such site. Drs. William L. Higgins, South Coventry, and Max Mailhouse, New Haven, have been appointed by the governor a committee.

Mental Hygienists Meet.—At the second annual meeting of the Connecticut Society for Mental Hygiene, held in New Haven, November 12, Drs. Seldon B. Overlock, Pomfret, and Frederick T. Simpson, Hartford, were reelected to fill vacancies in the board of directors, and W. Perry Curtiss was elected to fill the vacancy caused by the resignation of Dr. Elizabeth C. Spencer, Waterbury.

Monument to Inebriety-Cure Pioneer.—A monument was unveiled in the Wilton Cemetery, October 27, to Dr. J. Edward Turner, the first to urge the practical fact that inebriety is a disease, and who founded and built the first institution for the treatment of this disease. Dr. Lewis D. Mason, Brooklyn, N. Y., president of the American Society for the Study of Alcohol and Narcotics, delivered the dedicatory address, and the memorial address was made by Dr. Thomas D. Crothers, Hartford.

Dispensary Election.—At the annual meeting of the board of managers of the New Haven Dispensary Association, November 10, the following officers were elected: Dr. Arthur N. Alling, secretary; medical staff: surgery, Dr. Joseph M. Flint; medicine, Drs. George Blumer and Oliver T. Osborne; gynecology, Dr. Otto G. Ramsay; ophthalmology, Dr. Arthur N. Alling; neurology, Dr. Max Mailhouse; pediatrics, Dr. Harry M. Steele; dermatology, Dr. Ralph A. McDonnell; orthopedics, Dr. Frederick N. Sperry; and laryngology, Dr. Ernest H. Arnold.

ILLINOIS

Spitting Ordinance in Effect.—The municipal ordinance against spitting came into effect in Kankakee, November 26. By its provisions, a fine of $3 and costs is provided for the first offense, and a maximum fine of $23.25.

Tent Colony Disbanded.—The Tuberculosis Tent Colony at Peoria Heights has been disbanded and the patients have been discharged and have gone to their respective homes. During its existence the colony has had eight patients, all of whom showed marked improvement. It is proposed to reestablish the colony next year on a larger scale with accommodation for twenty or more patients.

Hospital News.—The campaign in Monmouth for a new hospital was inaugurated November 29. It is expected that $30,000 will be raised for the erection of the new building, and half of that amount has already been secured.——The people of Rochelle have subscribed $22,000 of the $35,000 required to make effective the offer from Emmanuel Hilb, the $15,000 for the establishment of a public hospital in Rochelle.

Retiring Railway Surgeon Honored.—Dr. Charles B. Fry, Mattoon, for many years local surgeon of the Illinois Central and Big Four railroads, who is soon to retire from practice and leave the city, was the guest of honor at a meeting of the railway employees of the city, held November 30. The superintendent of the St. Louis division of the Big Four presented Dr. Fry, on behalf of the employees, with a handsome traveling bag.

Chicago

Tuberculosis Clinic Changes Habitat.—The clinic of the Chicago Tuberculosis Institute, now held twice a week at the Northwestern University Medical School, was transferred December 6 to the Post-Graduate Hospital, Dearborn and Twenty-fourth streets. The clinic days and hours will remain the same, Mondays and Thursdays, from 10 a. m. to noon.

The Old, Old Story.—On information sworn to by three physicians, S. W. Jacobs and Harvey M. Brown, officials of the National Aid Society, were arrested November 30, charged with a new insurance confidence game. It is claimed that the complainants were induced to buy stock in the society on the representation that they would receive stock dividends, and furthermore that they were to be called when any of the subscribers were taken ill, and were to be paid liberally for these services.

INDIANA

Personal.—Dr. Paul F. Martin has been appointed a member of the city board of health of Indianapolis, vice Dr. Frank M. Morrison, elected a member of the board of school commissioners.——Dr. Franklin P. Gillaspy, Indianapolis, received painful injuries by being struck by a street car, November 6.

Medical Society Meeting.—At the annual meeting of the Thirteenth District Medical Society, held in Warsaw, Dr. Charles J. Loring, Rochester, was elected president; Dr. Lorenzo D. Eley, Plymouth, vice-president, and Dr. C. Norman Howard, Warsaw, secretary-treasurer. The next meeting will be held in Goshen.——Fort Wayne Academy of Medicine, at its annual meeting, elected Dr. Harold K. Mouser, president; Dr. Cecil C. Kimmel, vice-president; Dr. Willis W. Carey, secretary, and Dr. Charles G. Beall, treasurer.

IOWA

Hospital News.—A new wing to cost $10,000, is to be added to the Graham Hospital, Keokuk. It will contain fourteen rooms for patients, a large kitchen, dining-room, diet kitchen, and operating-rooms.——The Sisters of Mercy have assumed charge of the Centerville Hospital.

Personal.—Dr. Elijah W. Jay, Marshalltown, was operated on for the removal of gall-stones at Augustana Hospital, Chicago, November 23.——Dr. William W. Pearson was installed as dean of Drake College of Medicine, Des Moines, November 23.——Dr. Charles F. Dietz, Tabor, is reported to be seriously ill with neuritis.——Dr. Lacy K. Bobo, Oxford Junction, has been made president of the Iowa Sanatorium, Maquoketa.——Dr. John W. Smith, Burlington, sustained painful injuries in a runaway accident, November 10.——Dr. Elbert W. Clark, Grinnell, state senator, is reported to be seriously ill at his home.

District Societies Meet.—At the annual session of the Southeastern Iowa Medical Society, held in Mount Pleasant, November 20, it was decided to hold the next meeting at Fort Madison. The following officers were elected: Dr. Charles S. James, Centerville, president; Drs. William S. Lessenger, Mount Pleasant, and Alfred O. Williams, Ottumwa, vice-presidents; and Dr. E. Francis LaForce, Burlington, secretary-treasurer.——At the fifth annual session of the Second District Medical Society, held in Davenport, November 16, the following officers were elected: President, Dr. Lawrence W. Littig, Iowa City; vice-presidents, Drs. Elbridge H. King, Muscatine, and Gordon F. Harkness, Davenport; and secretary-treasurer, Dr. John V. Littig, Davenport (reelected). The 1910 meeting is to be held in Davenport.——Des Moines County Medical Society, at its annual meeting, held in Burlington, November 10, elected Dr. Charles P. Frantz, president; Dr. Fred E. Koch, vice-president; and Dr. Julia M. Donahue, secretary, all of Burlington.

KENTUCKY

Personal.—Dr. Henry Enos Tuley, Louisville, has been appointed by the governor a delegate to represent the state at the National Rivers and Harbors Congress, held in Washington, December 8-10. He has also been elected director of the Louisville Commercial Club.

Elections.—The Louisville Clinical Society held its annual meeting, November 23, and elected Dr. Joseph W. Irwin, president; Dr. William A. Jenkins, vice-president; Dr. Henry J. Farbach, secretary; and Dr. Argus D. Willmoth, treasurer.——Todd County Medical Society, at its annual meeting, held in Elkton, elected the following officers: Dr. John R. Crittenden, Gordonsville, president; Drs. Charles M. Gower, Trenton, and Walter E. Bartlett, Kirkmansville, vice-presidents; Dr. Lee P. Trabue, Elkton, secretary; and Dr. Robert L. Boyd, Pembroke, censor.

MARYLAND

Baltimore

Personal.—Dr. Paul W. Harrison has been appointed medical missionary to Africa by the Dutch Reformed Church.——Dr. James H. Stauffer is reported to be ill in Johns Hopkins Hospital.

Sanatorium Opened.—The Berliner Memorial Infirmary was formally opened November 22. Gen. George M. Sternberg, Surgeon-General U. S. Army, retired, Washington, received the building for the directors, and Emile Berliner, donor of the sanatorium, which is a memorial to his father, made an address.

Care of Insane.—A meeting was held December 9 in the hall of the Medical and Chirurgical Faculty to forward the movement for the study and care of insane and for provision of more hospitals. Addresses were made by Dr. William F. Drewry, Central State Hospital for the Insane, Petersburg, Va.; Attorney General Isaac L. Strauss, Dr. Thomas A. Ashby, Baltimore, member of the legislature; and Dr. DeWitt C. R. Miller, Cearfoss District, state senator. The State Lunacy Commission has drafted a bill for presentation to the next legislature, which calls for the formation of a permanent board of insanity, composed of five members and the attorney general, the members serving without pay. The board is to have power to remove persons from almshouses to asylums. The executive of the board is to visit all institutions at least once every six months. The state is to be divided into hospital districts, and jurisdiction is provided by boards of visitors for each county, and annual reports from heads of institutions. The cost and maintenance of white patients is fixed at $200 per annum, and that of colored patients at $150 per annum, of which the state is to pay one-half. The board is to receive $5,000 a year for expenses, out of which a salaried executive is to be paid. License is to be required from all asylums and retreats. In addition to the two present state hospitals, an additional one is to be provided for white persons on the eastern shore and one for colored persons in southern Maryland.

MICHIGAN

Personal.—Dr. Eugene Smith, Detroit, has returned from Europe.——Dr. George R. Pray, Jackson, has been elected supreme archon of the Phi Beta Pi Medical Fraternity.

Society Meeting.—At the annual meeting of the Genesee County Medical Society, held in Flint, October 26, Dr. Noah Bates, Flint, was elected president; Dr. James W. Parker, Grand Blanc, vice-president; Dr. Myron W. Clift, Flint, secretary-treasurer; Dr. Amos S. Wheelock, Goodrich, member of the board of directors, and delegate to the state medical society, and Dr. Herbert E. Randall, Flint, alternate.

Tuberculosis Records.—Under the new state tuberculosis law, record books are provided, giving case reports of tuberculosis, including the name and address of each patient, age, nativity, sex, occupation, color, place where last employed, evidence on which diagnosis of tuberculosis is made, part of body affected, stage of disease, and name and address of person furnishing facts. These registers are open to inspection only by the health authorities, and it is not permitted that any such reports or records shall be divulged so as to disclose the identity of the persons to whom they relate.

Tuberculosis Notes.—The Detroit Society for the Study and Prevention of Tuberculosis has concurred in the report of the sanatorium committee, recommending the acceptance of a ten-acre site at Twelfth and Hamilton boulevard. The institution will be known as the Detroit Tuberculosis Sanatorium. Articles of incorporation were drawn up November 16. Dr. Burt R. Shurly has been elected president, and Dr. Herbert M. Rich, a member of the executive committee.——The new shack at the Antituberculosis Camp, east of Kalamazoo, is ready for occupancy. The building is 25x25 feet and occupies the space between two other shacks. The institution now has three large and five small shacks in use.

NEW JERSEY

Fire in Epileptic Village.—Three of the five new barns on the grounds of the State Village for Epileptics, near Pennington, were destroyed by fire, November 9, causing a loss of about $20,000.

Oppose Preventorium.—The protest of certain residents of Lakewood against the Tuberculosis Preventorium for Children in that place has received the support of the governor, who states that the establishment of an institution of that character can be done only under state authority, and refers the matter to the Commissioner of Charities and Corrections for action.

Personal.—Dr. Hyman I. Goldstein, Camden, has been elected assistant laryngologist and assistant in the nose, throat and ear and medical departments of the Lebanon Hospital, Philadelphia.——Dr. William James, German Valley, was seriously burned while attempting to save his horses from a burning stable.——Drs. George C. Becket, Winifred D. Banks, and Palmer A. Potter have been appointed medical inspectors by the East Orange Board of Education.——Dr. Luther M. Halsey, Williamstown, has been appointed medical inspector of schools of Monroe township.——Dr. Horace G. Norton, Trenton, has been elected secretary of the State Board of Medical Examiners, vice Dr. Edmund L. B. Godfrey, Camden, resigned.

NEW YORK

Antituberculosis Society.—The Syracuse branch of the New York Association for the Prevention and Cure of Tuberculosis was organized November 26. Dr. David M. Totman presided and was afterward elected one of the vice-presidents of the association.

Personal.—Dr. George S. Lape has been elected jail physician of Binghamton.——Dr. Vernon L. Bishop, Hemlock, has been appointed physician at the Matteawan State Hospital. ——Dr. J. Reid Davidson, South Bethlehem, has retired after thirty years of practice.

Lockport Physicians Organize.—The physicians of Lockport have organized a local society, known as the Lockport Academy of Medicine, have adopted a constitution and by-laws, and elected the following officers: President, Dr. Charles N. Palmer; vice-president, Dr. Flavius J. Baker; secretary, Dr. Charles L. Preisch; treasurer, Dr. Henry H. Mayne; councilors, Drs. Allan N. Moore, S. Wright Hurd, and Alexander McNamara; and trustees, Drs. Ferdinand A. Kittinger, Willis P. Weaver and Warren H. Loomis.

Sanatorium and Hospital Plans Approved.—The State Board of Charities, at a meeting November 7, approved the certificate of incorporation of the Newburgh Sanatorium, to be established by ex-Gov. B. B. Odell, Jr., at a cost of $75,000. The board also approved the proposed consolidation of the New York Infant Asylum and Child's Nursery and Hospital, to be known as the New York Infant Hospital and Child's Nursery, with joint resources of about $1,000,000, and the incorporation of the Southampton Hospital Association, which proposes to establish a general hospital at Southampton, Long Island.

New York City

Harvey Lecture.—The third lecture of the Harvey Society, delivered by Prof. T. G. Brodie, of the University of Toronto, December 11, at 8:30 p. m., at the Academy of Medicine, 17 West Forty-third street, is on "Renal Activity."

Honor Retiring Intern.—Dr. Walter E. Hurley, whose term of service as house surgeon in the Williamsburg Hospital expired December 1, was given a farewell dinner, November 29, by professional and other friends, at which a colonial clock was presented to Dr. Hurley.

Andrew McCosh Memorial.—The Andrew J. McCosh Memorial Committee has announced that $116,000 have been received. The committee has not decided definitely on the memorial, but the fund probably will be used in the erection of an operating pavilion for the new Presbyterian Hospital.

For City Hospitals.—At the last meeting of the board of estimate the largest appropriation made was for the charities department, $2,237,000, which is to be used in improving the hospital facilities on Randall's and Blackwell's islands, and for improvements in connection with the Kings County and Cumberland Street hospitals.

Appropriation for Sanatorium.—The proposed tuberculosis sanatorium for the city at Staten Island took tangible form November 23, when the Board of Aldermen passed a resolution appropriating $1,300,000 in corporate stock for the building. The board also ratified the issuance of $54,000 corporate stock for the Coney Island Hospital, and $77,000 for the Bradford Street Hospital, Brooklyn.

Clinical Society Organized.—The Clinical Society of the West Side German Dispensary and Hospital was organized November 24. Its membership is composed of members of the staff and faculty of the New York Clinical School of Medicine. The following officers were elected: Dr. Robert N. Disbrow, president; Dr. Leon F. Garrigues, vice-president, and Dr. D. Livingston Morrison, secretary. The society will meet at the hospital on the first Tuesday of each month.

Large Sums for Charity.—The will of Edward O. Kindberg, recently admitted to probate, leaves the residue of his estate, worth about $100,000, to the Presbyterian Hospital.——The death of John Masterson Burke now makes available $4,000,000 for the building of a convalescent home. In 1902 Mr. Burke conveyed to a corporation which he named the Winifred Masterson Burke Relief Foundation, property to the value of $4,000,000, the income of which was spent in caring for worthy sick during his lifetime, but now the entire sum is at the disposal of the corporation.——The will of Herman Jacoby leaves $1,000 each to the Lebanon and Beth Israel hospitals.

Academy Needs Increased Facilities.—Because of the increase in membership of the New York Academy of Medicine, and the lack of space for the rapidly increasing library, it was proposed at a meeting of the directors, December 2, to submit to the members a proposition for the erection of a new building to cost about $700,000. The proposed improvements include an increase in the library space of from 90,000 to 225,000 volumes, and the enlargement of the present building by the purchase of the adjoining lot on the east. The president appointed the following committee to submit a report December 16, and suggest a site for the new building: Drs. Edward G. Janeway, Joseph D. Bryant, Abraham Jacobi, Algernon T. Bristow, Simon Flexner, Joseph A. Blake, Reginald H. Sayre, A. Alexander Smith, Charles L. Dana, Arthur M. Jacobus, W. Gilman Thompson, William C. Lusk, L. Emmett Holt, Herman L. Collyer, Henry S. Oppenheimer, Haven Emerson and Charles N. B. Camac.

NORTH CAROLINA

Personal.—After twenty years' service as surgeon general in the state, Col. Robert S. Young, Concord, has retired with the rank of brigadier general, and has been succeeded by Lieut.-Col. S. Westray Battle, Asheville, deputy surgeon general.——Dr. Francis J. Clemenger, Asheville, has returned from Europe.

The Tuberculosis Conflict.—At a meeting in Salisbury, November 20, the Rowan County Antituberculosis Association was organized. Dr. William W. McKenzie presided over the meeting, Dr. John Whitehead was elected president, and Dr. McKenzie, secretary.——Cumberland County Antituberculosis Society was organized at Fayetteville, November 13, with the following physicians as officers: Dr. Jacob F. Highsmith, Fayetteville, secretary-treasurer; and Dr. Kirby G. Averitt, Cedar Creek, second vice-president.——The North Carolina Association for the Prevention of Tuberculosis will hold its annual meeting in Greensboro, Jan. 25, 1910, under the presidency of W. L. Dunn. Dr. Livingston Farrand, New York, executive secretary of the national association, will deliver a popular address, and a tuberculosis exhibit will be held.——Dr. Charles A. Julian, secretary of the State Association for the Prevention of Tuberculosis, is holding special meetings and organizing local antituberculosis societies. He has requested all ministers to designate a day on which special sermons will be preached along sanitary lines. The governor commends the idea to the clergy. A Sunday in March is to be selected as *Sanitary Sunday*.

OHIO

Medical Teachers to Meet.—The Ohio Association of Medical Teachers will meet at the Southern Hotel, Columbus, December 27, afternoon and evening. Dr. James U. Barnhill is president and Dr. E. I. McKesson, secretary.

Personal.—While hunting near Marysville, November 23, Dr. Lutrelle M. Henderson was accidentally shot, but was not seriously wounded.——The board of trustees of the Toledo State Hospital has elected Dr. William H. Beggs, Columbus Grove, president, and Dr. George R. Love, Toledo, secretary.——Drs. Kinson S. West and Adams B. Howard, Cleveland, have started for Great Britain.

Cincinnati

Medical Research Society Election.—At the annual election of the Cincinnati Society for Medical Research, the following officers were elected: President, Dr. Paul Wooley; vice-president, Dr. William Wherry; secretary-treasurer, Dr. Jacob L. Tuechter, and executive committee, Drs. Sidney Lange and Joseph Ransohoff.

Celebrate College Union.—The union of the Ohio and Miami Medical Colleges was celebrated by the University of Cincinnati, December 1, at McMicken Hall. The chief address of the evening was delivered by Dr. Victor C. Vaughan, dean of the College of Medicine of the University of Michigan. A reception for the officers and guests of the University followed.

Personal.—Dr. Louis Schwab, mayor-elect, has resigned as medical director of the Cincinnati Hospital, and Dr. Byron Stanton, president of the State Board of Health, has been elected in his stead. Dr. Schwab was guest of honor at a banquet tendered by brother practitioners, November 24. Dr. Charles L. Bonifield acted as toastmaster and Dr. Schwab, in his response, spoke of the urgent need of an improvement in the sewage of the city.——Dr. Miriam Schaar, chief of the Bureau of School Hygiene, has resigned to take effect January 1.

PENNSYLVANIA

Philadelphia

Addition to the Mutter Museum.—A collection of vesical calculi and surgical instruments, formerly belonging to Dr. John B. Mettauer, Richmond, Va., were presented to the Mutter Museum of the College of Physicians by Dr. George Ben Johnston, Richmond.

Mutter Lecture.—The Mutter Lecture for 1909 will be delivered in the Cadwalader Room of the College of Physicians, December 10, by Dr. Henry D. Fry, Washington, D. C, professor of obstetrics in Georgetown University. His subject will be "The Nutritional Changes Occurring in the Fibromyomata of the Uterus Incident to Pregnancy and Puerperium."

Heavy Tuberculosis Mortality.—The large weekly mortality rate from tuberculosis has made it necessary for Dr. Joseph Neff, Director of Public Health and Charities, to ask Councils for appropriations to establish day camps for tubercular patients and for other preventatives and curatives. Of the total of 426 deaths reported last week, 117 were caused by tuberculosis.

New Hospital Plan.—A plan to affiliate the Philadelphia Polyclinic and College for Graduates in Medicine, known as the Polyclinic Hospital, with some other institution, was proposed at the last meeting of the directors. If carried out the institution will in the future be only a hospital and the college for graduates in medicine be dropped. The college and hospital were founded in 1883 and constitute the only institution of the kind in the state.

New Cars Decrease Accidents.—Figures have been compiled showing a year's operation of the Rapid Transit Company's pay-within cars, having the closed doors and steps. During the month of October on one line alone there was a decrease in accidents of 74 per cent. In the five heaviest months of the year, April, May, June, July and August, accidents on the Fifty-second street division decreased 79 per cent. compared with the same period of last year when no pay-within cars were used. The number of passengers on this line increased 11.2 to 12.5 per car mile. The greatest number of injuries have been caused by boarding and alighting from cars, a class of accidents entirely avoided by the pay-within car.

Old Hospital Corner-Stone Removed.—The corner-stone of the recently demolished executive building of the Municipal Hospital at Twenty-second and Lehigh avenues was taken from the old grounds, which are being converted into a public park, on December 3, and sent to the bureau of city property in City Hall. It was found to contain the daily papers of Feb. 1, 1864, together with a list of the members of Councils of that year and the names of city officials and the special commission, of which Dr. John B. Biddle was president, appointed for the purpose of obtaining a site and erecting a building for municipal hospital purposes. The ordinance was dated Nov. 24, 1862, and provided that the site should not exceed $10,000 in cost, and the cost of buildings was limited to $30,000. The site is now valued at $200,000.

GENERAL NEWS AND COMMENT

Colorado Medicine.—No reform is accomplished without self-sacrifice and often those who are most ready to assume the burdens are those who would seem least fitted to bear them. The Colorado State Medical Society is not the largest, strongest, or wealthiest of the state associations. Its members number only 778, and the publication of a journal of any kind by this society speaks well for the energy and devotion of its members. When, however, it publishes a periodical which, in the cleanness of its advertising pages as well as the scientific and practical character of its reading matter, can compare favorably with the publications of much larger associations, it is entitled to all the more credit. *Colorado Medicine*, the monthly published by the Colorado State Medical Society, is only in its sixth year, yet from the beginning it has kept a high standard for its advertising pages and has placed the good of its membership above its advertising receipts. The Colorado profession is to be congratulated on having had the right man to manage its official paper.

Chiari to Give Herter Lectures.—The next course of lectures on the Herter Foundation in Johns Hopkins Medical School, Baltimore, will be given Oct. 5, 6 and 7, 1910, by Dr. Hans

Chiari, professor of pathologic anatomy in the University of Strassburg. His subjects will be: (1) "Significance of the Amnion in the Origin of Human Monstrosities;" (2) "Necrosis of the Pancreas;" and (3) "Spondylolisthesis."

Mexican Association to Meet.—The International Medical Association of Mexico announces that its next meeting will be held at Aguascalientes, January 25-27. The officers of the association are Dr. S. H. Hodson, Tampico, president; Drs. C. L. Bennett, Aguascalientes, and J. McPherson, Salina Cruz, Oaxaca, vice-presidents; Dr. J. S. Steele, Monterey, N. L. secretary-treasurer; Drs. Carlos E. Husk, Santa Barbara, Chihuahua, C. E. Cramb, Mapimi, Durango, and R. H. L. Bibb, Saltillo, Coahuila, censors; and Drs. R. D. Robinson and W. R. Jamieson, Torreon, Coahuila, editors of the *Annual*. The work of the association is divided into three sections: first, "original articles;" second, "rehashes;" and third, "emergencies and mistakes."

FOREIGN

Association of Italian Medical Press.—The representatives of the various scientific journals published in Italy met at Genoa, October 24, to organize the Association of the Scientific Press with departments for the various sciences. The medical department has taken for its tasks a campaign against the pseudoscientific medical journals representing commercial interests, and the defense of the Italian language in international congresses.

Death of Duke Karl Theodor, the Royal Ophthalmologist.—Duke Karl Theodor of Bavaria, the well-known ophthalmologist, succumbed to kidney trouble on November 30, at Bayreuth in Bavaria. He was the head of the ducal line of the Bavarian house, and one of his sisters was the empress of Austria, assassinated a few years ago at Geneva; the other sister, the duchesse d'Alençon, lost her life in the Paris charity bazaar fire. One of his daughters is the wife of the crown prince of Belgium, and the other the wife of the heir to the throne of Bavaria. Duke Karl has published a number of good works on ophthalmologic subjects, and had an extensive practice, but charged no fees. He founded and sustained a free eye hospital for his patients. His seventieth birthday was celebrated August 9, on which occasion our Berlin correspondent reviewed his scientific career (page 807).

Other Deaths in the Profession Abroad.—A. O. Lindfors, who was professor of obstetrics and gynecology at the University of Upsala, died while on a trip to England, aged 67. He published a number of works on these specialties, both in Scandinavian and German journals, among them his account of the first successful operation for umbilical hernia.——L. Katz, professor of otology at the University of Berlin, and author of microphotographic atlases of the internal ear, etc., died in September, aged 61.——Prof. A. Dohrn, the founder and director of the Zoologic Station at Naples, the cradle of so much important biologic research by investigators of all countries, died at Munich September 26, aged 59. He is said to have been the first to call attention to the transformation of functions of organs.

Diplobacillus Alleged Causal Germ of Exanthematous Typhus. The *Centralblatt für Bakteriologie*, Oct. 30, 1909, contains an article by M. Rabinowitsch of Kief, Russia, on the local endemic of exanthematous typhus and announcing that he has been able to isolate from the blood and organs a diplobacillus which shows up with the Giemsa stain and induces in laboratory animals a disease closely resembling typhus in man. He states that poverty and destitution in Russia have reached their highest point in the last three years, and that endemic fevers have kept pace with them. Between 1900 and 1906 there were 1,515 cases of exanthematous typhus at Kief, with 124 deaths; 2,873 of typhoid, with 275 deaths, and 332 of relapsing fever, with 4 deaths. Since the beginning of 1906 to the beginning of 1909 there have been enough more cases to bring the totals for the last eight years to 3,261 cases of exanthematous fever, with 297 deaths; 6,118 of typhoid, with 734 deaths, and 13,574 of relapsing fever, with 397 deaths. Since April, 1908, there were in the local prisons alone 840 men and 27 women affected with exanthematous typhus. He assumes that germs lose or acquire certain properties by passage through the animal organism or by breeding in filth, and that poverty and unhygienic conditions, by reducing the resisting powers, favor endemics in general. In the overcrowded Russian prisons some of the men have to lie on the floor close up to the door near which is installed the historically famous "parascha," the can used by the prisoners for their excreta, and which is emptied only once a day. The political prisoners are kept separate, he says, and only a few among them have contracted typhus. The mortality in the prisons has been 23 per cent., while in the general population it was only 8.1 per cent. The distribution of the three endemic fevers throughout the town seems to show that the means of dissemination are practically the same for all. We fail to recognize the pathogenic germs when encountered outside of the body because they have lost certain properties by which we are accustom [illegible] specific bacillus seems to have a [illegible] he remarks.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Nov. 25, 1909.

The Infectious Nature of Infantile Diarrheas

Some authors have disputed the bacteriologic origin of infantile diarrheas and have attributed it to alimentary intoxication or to external causes, such as excessive variations of temperature. M. Metchnikoff, at the last session of the Academy of Medicine, made an important communication which tends to show the infectious nature of infantile diarrhea. He finds that suckling rabbits often contract a fatal diarrhea after having absorbed a small quantity of the dejections of infants affected with acute gastro-enteritis. A young chimpanzee which had been given a little of the green diarrheic injections of a baby of six months was abruptly seized with a severe diarrhea which lasted four weeks, and a second chimpanzee which was given some of the diarrheic matter of the first chimpanzee also had diarrhea the next day. According to the researches of M. Metchnikoff, the pathogenic microbe of gastro-enteritis is the *Bacillus proteus*. Hence, it becomes difficult to hold cows' milk responsible for infantile diarrhea, since out of every ten samples of cows' milk, only two contain the *Bacillus proteus*. Moreover, many cases of gastro-enteritis are observed in breast-fed children. It seems probable, therefore, that it is not cows' milk, but rather the persons who care for the infants who communicate the infectious agent to them. The *Bacillus proteus* is very abundant in the dejections of animals (the cow, dog, horse); it is probably carried thence by flies to various foodstuffs, such as raw meat, cheese, grapes, salad, vegetables, etc., which, eaten without being disinfected, carry the microbe into the alimentary canal. The prolonged contact of infected persons with infants is sufficient to contaminate the latter. To protect infants from gastro-enteritis, therefore, it is not sufficient to sterilize the cows' milk that is fed to them; it is necessary, also, that the hands and the breasts of the women who suckle them should be frequently washed with soap, and that the persons who care for the infants take precautions not to become infected with the *Bacillus proteus*. To this end M. Metchnikoff recommends washing fruits and vegetables, especially salad vegetables, with boiling water, and even singeing cheese crusts.

Limitation of the Number of Medical Students

At the next Congress of Practitioners, which will be held at Paris at the end of March. 1910, the question of limitation or non-limitation of the number of medical students who enter the schools will be discussed. In order to diminish the oversupply which seems to prevail in the medical profession, some physicians propose to establish competitive entrance examinations for the young people who intend to enter a medical career. As I have had occasion to show in a former letter, however (The Journal, Aug. 29, 1908, li, 771), the situation from which the medical profession in France suffers depends, not on the overproduction of physicians, but rather on the bad distribution, a greater number of young physicians seeking to settle in Paris and the large cities, where they drag out a miserable existence, when they might earn a livelihood in the country.

Medical Secrecy with Respect to the Insane

Dr. Pradel has laid before the *Syndicat médical de Paris* a delicate and embarrassing case. A physician had attended a married man who had become insane and had been placed in an institution. The patient had died, leaving a will disinheriting his widow, who, in order that she might contest the will, had asked the physician who attended her husband before he was placed in the institution, for a certificate stating that her husband had had mental trouble at a date anterior to that of the will. The question that Dr. Pradel raised was whether the family physician could give the widow a certificate to that effect. This communication called forth a warm debate and most dissentient opinions. Dr. Chassevant, professor *agrégé* at the Paris medical school, declared that the physician had not the right to deliver such a certificate, because it would be a violation of professional secrecy. Dr. Dalché, physician of the hospitals of Paris, believed that, whatever grounds there might be for giving such a certificate, the law forbade it. Dr. Biarbeau, on the contrary, believed that when a patient had been examined and declared insane, professional secrecy was no longer due to the patient, while his wife had a certain right to demand a certificate stating that there had been mental trouble dating from a certain time, consequently, the physician would not violate professional secrecy by granting it. Dr. Granjux, secretary of the staff of the *Bulletin Médical*, insisted that the first duty of the physician was to protect a patient with mental disease by making his condition known to the person who represented the family and indicating the precautions necessary to take. These precautions in reality constitute measures restrictive of individual liberty, and the guardian who executes them has an indisputable right, in order to justify his responsibility, to exact from the physician a written statement of the necessity of such measures. Even if the patient's guardian does not demand a certificate at the time, he might need and demand it later; and in such cases the physician can do nothing else than to protect the patient's representative from responsibility for the measures that he himself has prescribed.

The Public First Aid Service

Dr. Thoinot has just given to the Council on Public Hygiene and Salubrity of the department of the Seine a report on the work of the first aid service (*secours publiques*) during the year 1908. The pavilions established in Paris along the banks of the Seine and the canals for first aid to the apparently drowned have received 392 patients (228 men and 164 women), twelve of whom having been too long in the water could not be resuscitated; 165 of these had thrown themselves into the water. The stations established in the suburbs received 15 apparently drowned persons, of whom only one could not be revived. Of sick and wounded persons 260 (238 wounded and 28 sick) were cared for in the various first-aid posts of Paris. Ninety-five persons (88 wounded and 7 sick) were cared for in the suburbs. The special ambulances used at the time of public ceremonies and holidays received 326. The litters of the various stations of the arrondissements have been used 290 times. In short, the first-aid service has given aid during 1908 to 1,378 persons, 407 of whom had been apparently drowned.

Prizes of the Academy of Sciences

The Academy of Sciences has just awarded the following prizes: the Montyon prize ($150 or 750 francs) was divided between M. Charles Dhéré, professor of physiology at the University of Fribourg, Switzerland, for his "Spectrographic Researches on Absorption of Ultra-Violet Rays by the Albuminoids, the Proteids and Their Derivatives," and M. E. Pozerski, of the Pasteur Institute at Paris, for a work entitled "Contribution to the Study of Papain." The Philipeaux prize ($180 or 900 francs) was given to Dr. J. E. Abelous, professor of physiology at the Toulouse medical school and Dr. E. Barbier, professor *agrégé* at the same school for their works on "The Hypertensive Actions of Urines and Urohypertensin." The Lallemand prize ($360 or 1,800 francs) was divided between M. Auguste Petit (for his work on "The Brains of *Grampus griseus, Steno frontatus* and *Globicephalus melas*") and M. Gustave Roussy, of the school of higher studies at the College of France, for his work entitled "The Optic Thalamus, The Thalamic Syndrome." The La Caze prize ($2,000 or 10,000 francs) was given to Dr. Delezenne of the Pasteur Institute at Paris for his collective works. The Barbier prize ($400 or 2,000 francs) was divided between M. L. Launoy (for a series of works on the "Nuclear Phenomena of Secretion," "The Histophysiology of Pancreatic Secretion," "The Autolysis of Organs and Endocellular Ferments," and "The Aseptic Autolysis of the Liver") and M. J. Lesage, now professor of physiology at the institute of agronomy at Buenos Ayres for his memoir: "Experimental Researches on Maté." The Parkin prize ($680 or 3,400 francs) was awarded to M. Adolphe Cartaz for his memoir on "The Employment of Carbon Dioxid in Diseases of the Nose and Throat."

LONDON LETTER

(From Our Regular Correspondent)

London, Nov. 27, 1909.

The Declining Birth Rate

The president of the Royal Statistical Society, Sir. A. Baines, devoted his inaugural address to "The Recent Growth of Population in Western Europe." The population with which he dealt in 1900 numbered 239,000,000. During the last thirty years the Teutonic element has risen from 53 to 58 per cent. and the Latin has fallen from 44 to 40 per cent. Ireland alone shows an actual decrease of 17 per cent. The general increase is just under 31 per cent., conventionally held to have been normal for the last century. A generation ago the marriage rate was held to be a good barometer of prosperity and wherever there was room for a couple to live up to the conventional standard a marriage took place. But the standard of living and the power of convention over it has risen. On the whole there has been a slight falling off in the marriage rate during the last thirty years, which is especially marked among the already low rates of Scandinavia and in France and Italy. The increased avoidance of matrimony is most marked in the United Kingdom and in North Scandinavia. The mean age of wives has risen considerably in the United Kingdom but the decline of the birth-rate is still greater and cannot be accounted for by this cause. The rate of decline is even greater than in France. Until the present generation the systematic adoption of the limitation of offspring by married persons had been practiced only in the latter country. Now it has permeated this and other countries. As a result we are beginning to have in the green what is so apparent in the dry in France—an increasing preponderance of the population in or past its prime. In spite of the decreasing birth-rate a natural increase of the population continues, because everywhere the death-rate has fallen much faster than the birth-rate. Comparing the different countries the natural increase of population is greatest in Scandinavia, England and Holland occupy a middle position, and France falls behind the rest.

New Factory Act for India

The introduction of western industrialism into India has rendered necessary the adoption of regulations for labor analogous to those of European countries. The first factory act was passed in 1881. It provided for fencing of machinery, inspection and reporting of accidents, and limited hours of children's labor to nine. Seven was fixed as the lowest age for the employment of children, who remained in that category up to the age of twelve. In 1891 another act was passed raising the lowest age for the employment of children from 7 to 9, and the maximum age when they are considered such to 14. Their hours of labor were reduced to 7, the hours of women were limited to 11. A midday stoppage and a weekly holiday were prescribed for all hands. Except for the weekly holiday no restrictions were placed on the labor of adult males. There was no desire among the male operatives that their hours should be limited by law. Nature however imposed limits—the hours of daylight, which average about 12 throughout the year. But the introduction of the electric light has abolished this restriction. In 1904-05 there was a boom in the cotton industry in Bombay and the hands were overworked, though well paid. Adults, and sometimes children, worked as much as 15 hours daily or more and the conditions were denounced as a scandal and attracted public attention. The government, therefore, instituted an inquiry by a committee containing physicians and health officers, who reported in favor of a twelve-hour day. The committee found that the conditions of work in the textile factories were calculated to cause physical deterioration and it was struck by the absence of elderly men, although the demand for labor was much in excess of the supply. The government has now passed a new act limiting the hours of labor to twelve. Employment of women before 5:30 a. m. or after 7 p. m. is forbidden and, unless an approved shift system is adopted, of adult males also. Regulations are made for ventilation, lighting, water supply, latrines, protection against fire, etc. After six hours work there must be an interval of half an hour. A child must be examined and obtain a certificate before employment in a factory. No child must be employed more than six hours in a textile factory. The most important new departure is the regulation of the hours of adult labor. The Indian laborer prefers to work leisurely for long hours with frequent rests rather than work strenuously for shorter hours.

The Royal College of Surgeons

The annual meeting of the fellows and members of the Royal College of Surgeons has been held. The president, Mr. Henry Butlin, expressed doubts whether the proposed combination with the University of London for the purpose of rendering a medical degree more accessible to London students (referred to in a previous letter) was possible. Everything should be done to bring about this object by lowering the standard of examination for the benefit of students educated in London, who suffered great disabilities and disadvantages compared with those educated in the provinces and in

Scotland and Ireland, where a medical degree was obtained more easily. A long discussion took place on the granting of members the right of direct representation on the council (the governing body of the college). At present the council is elected entirely by the fellows, who form a small minority. These holders of the superior qualification are nearly all hospital surgeons and include practically all the names eminent in English surgery. The members number 17,000 and are nearly all general practitioners, the rank and file of the profession. The annual meeting of fellows and members is the only occasion on which the members have any opportunity of expressing their views with regard to the government of the college. For the past twenty-five years they have passed a resolution demanding representation on the council which has never been followed by any action by that body. The members urge that they contribute the largest amount of money (in examination fees) to the upkeep of the college and that their exclusion from representation is not in consonance with modern democratic ideas. However, no allegation has ever been made by them that government of the college is not carried on in the best possible manner and they have never suggested important reforms which should be carried out. Though [illegible] in the hands of an oligarchy it is an [illegible]est possible kind—an aristocracy of bra[illegible], examination is open to every member and requires only the requisite ability and knowledge. It may therefore be contended that the present government is democratic in the best sense. A resolution was also carried in favor of the promotion of a new charter and act of parliament for the incorporation of the Royal College of Surgeons and Physicians with the University of London with the object of facilitating the obtaining of degrees by London students.

Radium from Uranium

At the Physical Society of London, Mr. Soddy read a paper on this subject which is of interest in view of the therapeutic uses of radium. Measurements on the growth of radium in three uranium solutions purified between three and four years ago have shown that in all the growth of radium is proceding at a rate proportional to the square of the time. This result indicates the existence of only one long-lived intermediate product in the series between uranium and radium. The period of the average life of this body, calculated on the assumption that no other intermediate bodies exist, is 18,500 years.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Nov. 24, 1909.

The New Bill for the Care of the Insane

Our "lunatic act" (*Irrengesetz*), as it is called, is so behind the requirements of modern times that its reform is the first aim of the new chief board of health (*oberste Sanitäts Rat*). A reform of the clause dealing with the voluntary or involuntary admission of a person of unsound mind into a "sanitarium" is most urgently called for. In future the seclusion of a person supposed to be of unsound mind must be reported to the local authorities within twenty-four hours, if it be a member of the family, or within eight days, if it be a stranger. Then the public health officer has to examine the patient and to report to the board of health whether the person must be detained in a lunatic asylum or any other suitable sanitarium or may be left in charge of his friends. If the patient is dangerous to himself, those around him or the public, or he would be apt to suffer from neglect at home, he must be detained in an asylum. If the patient has no friends the local magistrates may at once order the detention, if the case is dangerous. The patient may be detained against his will or the will of his friends under the following conditions: If the officer of health finds it necessary; if a public judge orders it after hearing medical evidence; if the legitimate representative or guardian of a person under age requires it; or if a person traveling on a railroad or other public conveyance is found to be of unsound mind and the health officer considers him a public danger. Any such case must be reported at once to the board of health, for as the first sentence of the new law says, "all persons who on account of a defect of their mental capacities require special care enjoy the protection of public administration." For this purpose a special inspector for the mentally afflicted (*Irreninspector*), with assistants, will be appointed on the board of health. It is therefore intended to institute a psychiatric sanitary board. The official name of an institution for the insane will no longer be "lunatic asylum," but "sanitarium" (*Heil- und Pflegeanstalt*). If a person desires to be detained voluntarily in a mental sanitarium, a request must be signed by the patient himself, and a testimony by a qualified medical man, who is related neither to the patient nor to the owner or director of the sanitarium, must be produced. Such cases also must be reported within twenty-four hours to the inspectorate mentioned above.

Personal

The newly elected chief board of health, which for the first time since its existence contains also a number of country practitioners, held its first meeting for organization a few days ago, and Prof. Ernst Ludwig, the chief analytical chemist of the University of Vienna, was elected president, and Professor Weichselbaum, the well-known pathologist, vice-president, together with Professor Chrobak. Professor Horbaczewski was elected president of the committee for water-supplies, Mauthner, vice-president, Professor Exner, the celebrated physiologist, was elected president of the committee for health resorts, mineral waters and balneologic matters.

The Reform of Contract Practice and the Profession

A subcommittee of the Austrian parliament recently discussed the new arrangements suggested in connection with the proposed "social insurance bill." Representatives of medical councils and organizations were admitted to the inquiry. While employers and employees are willing to concede to the profession only that persons earning more than 4,800 crowns ($960) a year should be exempt from the compulsory insurance against sickness, the doctors wish the limit to be 2,400 crowns ($480). It must be kept in mind that in this country income taxes must be paid from an income of 1,200 crowns, or $240, showing that living is cheaper than in America, since this sum is considered enough to live on. More than 73,000 persons in employment, who are not members of a *Krankenkassa* or sick benefit club, earn over 2,400 and less than 4,800 crowns, so that this important class of the population would be lost for the profession as possible patients. This would mean the ruin of the profession. The figures are official. The government plan favors the lower figure as limit for the compulsory insurance. No consensus of opinion being obtained at the inquiry, and the parliaments being willing to disregard the interests of the profession, energetic measures are contemplated by the organization of practitioners, a young but active combination of doctors. In fact, if the law should pass the house and not pay due consideration to our profession, a general strike is already spoken of. But it is hoped that such a step will not be necessary.

Pharmacology

MORE PRESCRIPTION FAKES

Answers to Correspondents as a Means of Exploiting Nostrums

One of the "features" of the modern metropolitan daily is the "Woman's Page," in which is given, for the education or delectation of feminine readers, reading matter that ranges from the useful to the inane. Naturally enough, we find the important subject of care of the health learnedly (?) discussed by the "Madames" or "Mademoiselles" who have charge of these departments. To the "patent-medicine" advertiser who would deceive the reader by publishing his advertisement in "reading-matter" style, space on these "woman's pages" is a valuable asset. A form of deceptive advertisement that of late has become very popular with nostrum exploiters has previously been referred to in these columns as "prescription fakes." The advertisements are usually set as reading matter and contain information regarding the treatment of some physical ailment by means of the drugs contained in an innocent looking formula; usually all the drugs but one are official, the exception being a "patent medicine" with a name not unlike the pharmacopeial preparations. A modification of the "prescription fake" type of advertisement forms the subject of this article.

"HEALTH AND BEAUTY TALKS"

For several months past many newspapers have been carrying on the "woman's page" what, to the uninitiated, appears to be a department devoted to answering queries regarding health. The "department" is entitled "Health and Beauty

Talks," or "Health and Beauty Helps," or "Aids" or "Secrets"—the last word of the title varying with the copy. Under the title is the legend "By Mrs. Mae Martyn." The subject-matter consists of information (?) on questions of health, given in the "answers to correspondents" form; the first and last "answer" usually makes reference to none but simple home remedies or pharmacopeial preparations. For instance:

> Q.: A good foot wash is made of a pint of water, to which are added a tablespoonful of salt and a pinch of alum and a few drops of arnica.

Every other "answer," however, contains a "joker" in the form of a nostrum, which is referred to in such a way as to lead the unsuspecting reader to imagine that it is but an ordinary official drug. Thus, in the advertisement before us, there are nine replies. Here is a sample:

> Ethel J.: (1) It made me happy to read your letter. I am glad you think so well of my recipes that you cut them out and pass them along to your friends. None should have difficulty in getting from her druggist any ingredient I name, for I never advise the use of anything that is not sold in first-class drug stores everywhere. (2) The only objection I know to the use of liquid complexion beautifiers is their high cost when purchased in a ready manufactured state. You can make at home a fine "liquid powder" that softens and whitens the skin by putting 2 teaspoonfuls of glycerin and 4 ounces of spurmax in ½ pint of boiling water; let stand until cold. Apply with the palm of the hand and rub until dry. I prefer this spurmax wash to any face powder I can buy.

The "joker" in this "answer," of course, is spurmax. In the other "replies," all worded in the same deceptive way, the reader is urged to get:

Crystos: for "tired and inflamed eyes."

Almozoin: for "blackheads . . . freckles and tan."

Canthrox: "for shampooing purposes."

Quinola: "to remove dandruff, stop falling hair, relieve itching . . . and promote the growth of hair."

Parnotis: "a flesh reducer that . . . should reduce your weight 10 pounds in a few weeks."

Kardene: "a splendid blood tonic and liver invigorator . . . for pimples, yellow blotches, sallow complexion, scrofula and all eruptions of the skin."

Luxor: "a very dear friend of mine cured a most obstinate case of eczema with this remedy."

Every week or so "Mrs. Mae Martyn's" fake department will appear in the paper, the initials of the "correspondents" and the wording of the "answers" varying, but the usual changes being rung on spurmax, crystos, almozoin, canthrox, quinola, parnotis, kardene and luxor.

Should the innocent reader go to the drug store and ask, say, for four ounces of spurmax, she is given the inevitable "original package," consisting of a tin box bearing a label with the name of the preparation, the method of using it and the various conditions for which the nostrum is recommended. There is also the statement: "made by H. S. Peterson & Co., 95-97 Kinzie St., Chicago." The company putting out these medicinal agents is not a firm of pharmaceutical chemists, but, we understand, manufactures flavoring extracts and does business largely by means of women agents throughout the country.

Four of these deceptively advertised nostrums were analyzed in the Association's laboratory. The laboratory report follows:

ALMOZOIN

Almozoin, as found on the market, is a pale pinkish-white powder, having a faint odor like benzaldehyd. Qualitative examination of almozoin demonstrated the presence of magnesium, sodium, tragacanth, a carbonate and a borate. Free boric acid, ammonium salts and sulphates were absent. Magnesium and the borate radicle were determined and the tragacanth was approximately estimated. From the results of the examination it would appear that the composition of almozoin is essentially as follows:

Tragacanth (gum tragacanth)	40 per cent.
Sodium borate (borax)	40 per cent.
Magnesium carbonate	20 per cent.

[Retail price of almozoin, one-half dollar; estimated cost of ingredients, three cents.]

CRYSTOS

The specimen package of crystos which was purchased contained about one ounce and was a coarse, *white, odorless* powder. Qualitative tests demonstrated the presence of chlorid, free boric acid, borate, sodium and traces of sulphate. Alkaloids, ammonium salts, carbonates, heavy metals and potassium were absent. Determinations of chlorid and of free and of combined boric acid were made, from which it would appear that the composition of crystos is about as follows:

Dried sodium borate (dried borax)	20 per cent.
Sodium chlorid (common salt)	20 per cent.
Boric acid	60 per cent.

[Retail price of crystos, one-half dollar; estimated cost of ingredients, one cent.]

PARNOTIS

Parnotis is a pale, cream-colored, fine powder, having an odor resembling cologne, which dissolves in water and forms a turbid solution, which becomes clear by filtration. Qualitative examination of the preparation demonstrated the presence of a bicarbonate, sulphate, sodium and traces of chlorid and of iron. Quantitative determinations of the sulphate and of the bicarbonate were made, from the results of which it would appear that parnotis consists essentially of:

Impure anhydrous sodium sulphate	25 per cent.
Sodium bicarbonate	75 per cent.

[Retail price of parnotis, one-half dollar; estimated cost of ingredients, less than two cents.]

SPURMAX

Spurmax is a pink, crystalline powder, highly perfumed. Qualitative tests demonstrated the presence of magnesium and of a sulphate. The absence of more than traces of chlorid, carbonate, organic compounds and heavy metals was shown by the usual tests. Quantitative determinations were made for magnesium, for sulphate and for water. Microscopic examination indicated that the coloring matter was very unevenly distributed throughout the preparation, some crystals being colorless, while others were very highly colored. Essentially, spurmax consists of:

Crystallized magnesium sulphate (Epsom salts)	100 per cent.
Perfume	trace
Coloring matter	trace

[Retail price of spurmax, one-half dollar; estimated cost of ingredients, one cent.]

NEW FORM OF AN OLD TRICK

Spurmax, then, when subjected to the critical light of analysis and shorn of the hypothetical virtues with which "Mrs. Mae Martyn" invests it, proves to be Epsom salts colored pink and rendered highly odoriferous; the "flesh reducer that . . . should reduce your weight 10 pounds in a few weeks," contains, apparently, nothing more marvelous than sulphate and bicarbonate of soda—and so it goes. The old, old trick of the charlatan, the quack and the nostrum exploiter is again in evidence: Give some well-known drug a fancy name, disguise it physically if possible, advertise it as possessing marvelous virtues and sell it at a price out of all proportion to its value.

The petty dishonesty shown in the method of exploiting these nostrums by means of a fake "woman's department" is disgusting. That otherwise reputable newspapers should sell their pages for such a bare-faced deception and defraud their readers by giving editorial sanction—for that is what a fake "answers to correspondents" department does—to a "patent-medicine" humbug, does not tend to increase one's confidence in the daily press. It is but fair to say, however, that some of the more particular papers insist on making plain to the reader that the thing is an advertisement, either by placing the abbreviation [Adv.-] after the last "answer," or else by placing the matter on a page given over wholly to advertising. Such a course at least gives the reader some protection, as any advertisement inspires the attitude of *caveat emptor*.

Doubtless the financial returns from this style of advertising are a potent influence with those newspaper proprietors who are willing to carry this matter in the form of an original department. Advertisements as "straight reading matter" come high, but the profits derived from the sale of Epsom salts at $2 a pound are probably sufficient to bear it. Meanwhile, the "ultimate consumer," as usual, pays the bills.

BOARD OF TRUSTEES OF THE U. S. PHARMACOPEIAL CONVENTION

Report of the November Meeting

The Board of Trustees of the United States Pharmacopeial Convention met at Hotel Walton, Philadelphia, November 26 and 27, with the vice-chairman, James H. Beal, in the chair, and the secretary, Murray G. Motter, recording the proceedings. Members present were as follows: James H. Beal, Scio, O.; Frederick W. Meissner, Jr., LaPorte, Ind.; Joseph P. Remington, Philadelphia; George H. Simmons, Chicago, and Henry M. Whelpley, St. Louis. H. C. Wood and Charles E. Dohme were absent, owing to illness.

The secretary was instructed to notify a publisher who had failed to recognize the copyright of the Pharmacopeia that the matter would be placed in the hands of an attorney unless the terms of the agreement were complied with by the publisher at once.

The board approved of a form of credentials to the 1910 convention, as presented by the committee on credentials.

It was decided to submit to the 1910 convention an amendment to the constitution which, if passed, will admit delegates from the Department of Agriculture of the United States Government.

Requests were received from numerous other bodies not entitled to representation in the 1910 convention under the present constitution. The board of trustees was requested to take the necessary steps to present to the convention an amendment to the constitution which, if passed by a three-fourths vote of the convention, will entitle these organizations to representation. After discussion, definite action was postponed until the January meeting.

The board of trustees considered other recommendations to be made to the 1910 convention and gave special attention to the subject of size, constitution and work of the committee on revision. Formal action was postponed until the next meeting.

The committee on credentials and arrangements for the 1910 convention met and organized by the election of Oliver T. Osborne, chairman, and Murray Galt Motter, secretary. H. C. Wood, Jr., Samuel L. Hilton, James H. Beal, W. L. Cliffe, and H. M. Whelpley were also present. A synopsis of the proceedings, with information about the appointment of delegates will be furnished the medical and pharmaceutical press by the secretary of the committee, in the near future.

Henry M. Whelpley,
Secretary U. S. Pharmacopeial Convention.

Correspondence

Meat Extracts and Beef Juices

To the Editor:—The editorial on this subject and the excellent work referred to on the same subject by the Council on Pharmacy and Chemistry (The Journal, Nov. 20, 1909, liii, 1744, 1754) are a timely warning to the medical profession. Some of the points presented, however, are not sufficiently emphasized and may even be misleading. The article presents the main objection to meat extracts and juices to be on account of probable starvation to the patient using them; it is stated (page 1744) that "it is even more important to *note the* surprisingly low calorific value" of meat extract and (page 1756) that "the physician is deceiving himself, starving his patients," etc.

More recent research shows that "starvation" is not the only danger in the use of such preparations, but that the extractives themselves are toxic to the body, either on their own part or by increasing bacterial growth in the gastro-intestinal tract, which results in a still further elaboration of substances acting like toxins.

In preparing meat juice for consumption, it is necessary to take 2.9 to 3.9 per cent. extractives (Bulletin No. 21, U. S. Dept. Agricult.) in order to obtain 2.19 to 6.97 per cent. of coagulable proteids, varying according to the method of expression. And the conclusion that such meat juice might have considerable value as food is open to serious objection on account of the simultaneous intake of so large an amount of toxic substance.

In the threatening convulsions of uremia, cholemia, eclampsia, etc., it is strictly contraindicated to prescribe meat juice, bouillons, or other foods containing meat extracts, on account of the danger of precipitating a convulsive attack and death In many chronic conditions, such as gout, rheumatism, arteriosclerosis, kidney and liver diseases, appendicitis, ulcer of the stomach or duodenum, and in many nervous diseases, meat and meat juices are positively contraindicated.

In the surgical clinics in certain districts in Europe I recently observed a series of operations on the kidney, and several surgeons made the statement that the large number and severity of kidney lesions are due to the free use of meat juice, soups and gravies.

The extractives of meat are becoming a national question as concerning the etiology of groups of diseases which can be referred to meat-eating people. Watson Chalmers has graphically described the meat-eaters' zone and has shown an increase in disease peculiar to those who indulge in meat and meat extractives, but not peculiar to the people of those countries where nitrogen is obtained from vegetable proteins.

Rothberger concludes that the toxic symptoms of meat extract are due to some substance which the liver destroys (*Ztschr. f. exper. Path. u. Therap.*, 1905, i, 312-359). Pawlow observed that the ingestion of meat by an Eck-fistula dog was followed by a series of toxic symptoms.

Lieblein destroyed liver cells by injecting acid into the hepatic ducts, and toxic symptoms followed ingestion of extractives (*Arch. für exper. Path. u. Pharmakol.*, 1894, xxxiii, 318). Macleod noted a large amount of albumin in the urine of an Eck-fistula dog following addition of meat extract to the diet ("Studies in Pathology," Quarter-centenary of University of Aberdeen, 1906, p. 267). Salaskin believed ammonia to be the prime factor in causing the toxic symptoms (*Ztschr. f. physiol. Chem.*, 1898, xxv, 449). Pawlow injected sodium carbamate into the circulation of Eck-fistula dogs with negative results. Hawk repeated the injections and abandoned the theory. He fed Eck-fistula dogs with large amounts of meat extract (20-50 gm. daily for six to eight days) and obtained typical toxic symptoms which terminated fatally (*Am. Jour. Physiol.* 1908, ii, 21).

The injection of meat extract or any of the meat bases into the circulation has resulted negatively in demonstrating the presence of any special toxic body. It has been suggested that purin bodies and uric acid are derived directly from food rich in nucleins and extractives, but recent experiments have shown that these bodies can be formed synthetically from ordinary proteid. H. Trautner, after extensive research, is convinced that uric acid is the result of the activity of the colon bacillus in making reducing substances which undergo chemical changes in the blood. In 22 young rabbits he found no appreciable uric acid in the urine when no colon bacilli were present in the feces, but uric acid appeared when the animals were given colon bacilli added to their food (*Ugeskr. f. Laeg.*, Copenhagen, Sept. 23, lxxi, 1049-1070).

In my own experiments in which meat extractives or meat peptones were injected into dogs, the results were negative. Also injections of living or dead cultures of *Bacillus coli*, intravenously, subcutaneously or intraperitoneally, were negative. But when meat extracts and cultures of *Bacillus coli* were given together with food to dogs, over a definite period of time, lesions of the kidney, liver and stomach resulted and invariably death of the animal.

I have also fed meat extract to mice and rats, with the addition of cultures of *Bacillus coli*, and obtained toxic symptoms resulting in death. In these experiments, on account of increased growth of intestinal bacteria, the bacteriologic factor could not be ignored. It was plain that the meat extractives increased the numbers and activity of the intestinal bacteria. Extract-free meat was fed to animals and the bacterial content of the intestines decreased and no pathologic conditions followed (The Journal A. M. A., June 9, 1906, xlvi, 1753; *Jour. Med. Research*, xvii, No. 4; *Brit. Med. Jour.*, April 20, 1907).

The harmful effect of meat juice, therefore, must be chiefly due to the increased bacterial growth which it causes in the alimentary tract, and the symptoms which follow are more the nature of toxemia than starvation. If patients to whom meat juice would be prescribed are instead given extract-free meat, not only is the danger of extractive poisoning avoided, and of a resulting intestinal toxemia, but the concentrated protein quickly nourishes the patient.

Fenton B. Turck, Chicago.

Umbilical Hernia

To the Editor:—The report of Catchings' case of congenital umbilical hernia (abstracted in The Journal, Nov. 20, 1909, liii, 1779, from *Miss. Med. Month.*, November, 1909) recalls a case of my own. On Feb. 1, 1900, I delivered a baby boy of average size, with an umbilical tumor, larger, I think, than the one reported by Catchings. The contents of the sac were not adherent, and the various organs could be plainly seen through the translucent walls. I plainly recognized a portion of the liver, the spleen, stomach, colon and small intestines. The abdomen seemed entirely empty.

The contents were easily reduced and the cord sac tied very close to the abdomen and trimmed off, boracic acid freely applied and a thick firm pad and bandage put on. The child had no trouble and is to-day a strong healthy boy, with normal umbilicus and abdominal walls. For a while, however, the condition puzzled and worried me. It was my first and only case of that kind.

F. S. Smith, Nevada, Iowa.

Miscellany

A New Blood Test

The importance, for forensic and clinical purposes, of the detection of blood, has led to a great multiplication of blood tests. Most of the substances used for this purpose depend on the power of the blood to carry oxygen from some oxidizing substance to another substance which develops a characteristic color by oxidation. The more important substances used for this purpose in a clinical way have been guaiacum, aloin, benzidin and phenolphthalin, while the oxidizing agent used has usually been turpentine or hydrogen peroxid. A serious objection to the use of guaiac and similar substances has been the great number of substances other than blood which may produce the change in color.

In discussing this matter, J. H. Kastle[1] states: "The general consensus of opinion among those who have given this subject their attention, would seem to be, therefore, that the guaiacum test for blood and similar color reactions are valuable, especially if they lead to negative results, as proving beyond the peradventure of a doubt that blood is absent. On the other hand, if a positive test is obtained, care should be taken to exclude oxidases or peroxidases by boiling, and the salts of the heavy metals and other oxidizing agents by chemical methods, and, if possible, to subject the material under investigation to confirmative tests for blood before finally concluding that blood is present."

Kastle's investigations of the various blood tests lead him strongly to recommend the phenolphthalin test. Phenolphthalin is a product of the reduction of phenolphthalein by means of zinc and sodium hydroxid. When oxidized in alkaline solution it is converted into pheonolphthalein, which gives a red color. The test has about the same delicacy as the benzidin test. In the presence of blood and hydrogen peroxid a red color is almost immediately produced. If blood alone without an oxidizing agent is present the reaction occurs more slowly. Kastle found it possible to prepare a fairly stable colorless alkaline solution of phenolphthalin. A solution of alkaline phenolphthalin containing hydrogen peroxid was prepared which could be preserved for forty-eight hours, if kept in glass-stoppered bottles, in a dark closet at ordinary temperatures. In some cases it was found that with certain specimens of distilled water a coloration, ranging from pink to red, was produced in the reagent as soon as the hydrogen peroxid was added. The reason for this appears to be the presence of very small amounts of copper. To obviate this difficulty the water was redistilled in glass vessels.

Kastle found that the oxidation of phenolphthalin in alkaline solution by blood alone and in the presence of hydrogen peroxid, was considerably retarded by extracts of various animal tissues. The reason for this action is not known, but it may reasonably be attributed to a reducing action on the part of the tissues. At any rate, the detection of blood is markedly interfered with by the presence of certain organic substances of animal origin. Certain specimens of urine known to contain blood failed entirely to give the reaction with phenolphthalin. In no instance has a method of blood testing been devised which will recognize in urine, feces, gastric contents, etc., as small an amount of blood as can be detected in water. Various methods of removing blood from such mixtures have been tried. Thus Heller tests for blood in urine by precipitating the phosphates by alkalies which carry down the blood with them. Kastle uses for this purpose a small amount of aluminum hydroxid. To the separated sediment he applied the phenolphthalin test, and he found that, used in this way, it was very delicate.

For clinical purposes it is quite possible for a blood test to be too delicate, while many possible fallacies may be excluded by the known circumstances under which the test is applied. For forensic purposes, however, all possible fallacies must be guarded against. The phenolphthalin test has been objected to on the ground that many other substances besides blood will respond to it. Kastle finds that most of these substances can be excluded by boiling the mixture; the others present certain differences of action by which they can be easily differentiated from blood. By applying the test to unknown stains prepared by another chemist, Kastle found that he could readily detect blood with certainty. The test bids fair to be a valuable addition to our resources.

Rôle of Leucocytes in Absorption and Elimination of Medicaments.—The facts which have been gathered by a considerable number of observers regarding the action of leucocytes in the absorption of medicines are collected in a very interesting article by Arnozan and J. Carles (*Revue de Therapeutique Medicochirurgicale*, Aug. 15, 1909; *Journal suisse de Chimie et pharmacie*, Aug. 28, Sept. 4 and Sept. 11, 1909). Besredka has shown that the leucocytes absorb by phagocytosis the insoluble granules of arsenic trisulphid, thereby delaying the death of animals fatally poisoned and assisting in the recovery of others if the dose is not too large. Landerer has shown that leucocytes take up the balsam of Peru injected in a state of fine subdivision, and Arnozan and Montel have made similar observations with reference to iodoform and calomel. Oils and milk and medicated fat, such as mercurial ointment, are similarly affected, according to J. Carles. Soluble salts may be absorbed in the same way. Thus salts of iron, silver, mercury, sodium salicylate, atropin, lecithin, etc., are taken up by the leucocytes and unevenly distributed throughout the body. The leucocytes do not always show the same tendency to absorption toward all medicines, and their activity may differ in different species of animals. The medicaments absorbed by the leucocytes may undergo various changes; they may be transformed within the leucocytes by the action of various ferments which these cells contain. They may be carried to the various tissues and may be eliminated by the various excretory organs. One point of great interest is the tendency to elimination at the seat of injury where the leucocytes collect according to the great chemotactic laws. By this means the accumulation of a medicine in an unusual concentration at the seat of a pathologic process may determine either remedial processes, or if the dose be too large, aggravation of the disease may occur. The fate of the leucocytes which absorb the various remedies is various. They may act simply as carriers or they may become temporary depots of the foreign substances, or lastly, they may emigrate with their charge of toxic material, passing into the intestines and becoming lost. The therapeutic suggestions based on these investigations are both interesting and important. The action of the leucocytes would make untenable the prevalent doctrine that medicines absorbed into the system are equally distributed throughout the tissues. It would seem probable that, on the other hand, the distribution may be very unequal. It is of especial interest to note that the tendency of leucocytes to collect about an inflammatory focus or other lesion allows of an efficient curative action by a small amount of medicament without an injurious effect on the system in general. For local affections remedies should be preferred which will be taken up by the leucocytes; on the other hand, general infections, toxemias, etc., may escape the action of remedies, because the toxins or bacterial agents producing the disease float free in the blood stream, while the drug which should neutralize or destroy them is locked up in the leucocytes. Another idea springing from this conception is that the leucocytes may take up food substances and become incapable of absorbing medicaments, or may have become so saturated with drugs that they lose their phagocytic power. Metastases and the action of derivatives may be explained by supposing that leucocytes carry toxins from one point to another.

---

[1] Bull. 51, Hyg. Lab., U. S. P. H. and M.-H. S., Washington, D. C.

The Electric Forces of Mitosis and the Origin of Cancer.—"Although exception may be taken to any conclusions which are drawn from purely statistical data, yet it would appear that the evidence so arrived at is overwhelmingly in support of the fact that one of the major predisposing causes of cancer is to be found in close inbreeding. Moreover, it would also appear from a detailed comparison of the organs attacked, that those organs which are subjected to stresses and irritations are most liable to develop malignant growth. Both of these conclusions are in close agreement with the theory of electrocytology." Thus are characterized the main factors in an etiologic consideration of cancer in an elaborate paper by A. E. and A. C. Jessup, E. C. C. Baly, F. W. Goodbody and E. Prideaux (*Bio-chem. Jour.*, July, 1909, iv. 191). By these observers normal somatic cell division is explained as the result of well-balanced electric forces which have their origin in electrically charged cellular colloids. When this balance is sufficiently disturbed by external influences, continuous atypical cell division is the rule and a pertinent predisposing cause of cancer is established. The phenomenon of sex production is attributed to these residual colloid charges, and all the phenomena of parthenogenesis, artificial fertilization, pathologic mitoses and sterilization by *x*-rays are explained by the same theory. The daughter cells of the pseudo-reducing pathologic mitosis possess renewed activity. They possess potential probability of conjugation with leucocytes and normal tissue cells. To these latter, together with the stimulation of the surrounding tissue cells by the degradation products of cancer cell metabolism, is attributed the formation of a neoplasm with power of continuous growth. The susceptibility of the cell to derangement is increased with decreasing vitality, such as occurs with age, and as a result of inbreeding. The rate of proliferation depends on the activity of the cytoplasm; the greater the activity the more rapid the growth, while the more highly differentiated the cell and the older it is the less rapid the rate of proliferation. As a concise summary: age incidence, local origin, infiltration, metastases, transmission with all its limitations, and power of continuous growth are the natural outcome of abnormal cell proliferation induced by a disturbance of the electrostatic forces present in normal mitosis.

Glycogen in the Hypophysis and the Central Nervous System.—From a microscopic study of human, sheep and calves' hypophyses, stained with specific stains, W. Neubert (*Beitr. z. path. Anat. u. z. allg. Path.* 1909, xlv, 38) finds that glycogen occurs normally in the hypophysis. It is constantly found in the epithelium of the colloid cysts lying in the boundary zone between the anterior and posterior lobes, in the cysts themselves where a desquamation of epithelium has taken place, and in the colloid which results from this desquamation and transfusion. It is also found in the so-called nervous portion of the hypophysis, both within the glia cells and within the intercellular tissue of the posterior lobe. This latter occurrence of glycogen is indicative of the origin of the corpora arenacea and the corpora amylacea of the hypophysis. In pathologic conditions, as, for example, in diabetes, the percentage of glycogen is markedly increased and glycogen is then found in the parenchymal cells of the anterior, glandular lobe. Likewise, in diabetic subjects, glycogen is found in appreciable quantities in the brain, spinal cord and in the heart muscle, particularly in the lymph spaces, even though the blood contains only extremely small quantities. The occurrence of glycogen in the cystic epithelium and in the nervous portion of the hypophysis, Neubert thinks, is an expression of the embryonal nature of these tissues, of a primitive type of metabolism of the embryonal-like cells and the absence of any high degree of specialized functional activity. Glycogen formation in the liver is a product of a well-differentiated organ adapted to supply a simple primitive food for the nourishment of all the organs. Glycogen formation in any other organ, which is usually at the organ's own expense, represents a reversion from a highly specialized toward an embryonal state in an attempt to make good a deficient food-supply. This is especially true in diabetes.

The Effect of Autocondensation in Diabetes Mellitus.—Dr. F. deKraft, New York, at the recent meeting of the American Electro-Therapeutic Association, after citing 3 cases in detail, made the following deductions: Sugar and other products of impaired metabolism circulating in the blood in greatly increased amount act as irritants to the walls of the arteries, bringing about a form of arteriosclerosis closely resembling the senile form. High-frequency currents, applied preferably by autocondensation, or by the effleuve to insulated patient with grounded metal to back, regulate the circulation when it is unbalanced through profound influence on the sympathetic nervous system, improve the tone of the arterial wall, lower blood pressure, check the formation of toxins and strengthen the natural defenses of the body. They have a marked stimulating action on cell life and on the nutrition of cells at the farthest point. They increase the reducing power of hemoglobin, thus increasing oxidation in the tissues. Greater activity occurs in the kidneys and other glands, and there appears for a time more sugar in the urine, continuing until such time as the glycogenic balance in the liver cells and muscles is restored, after which, under continued treatment, the amount of sugar excreted steadily diminishes, and in favorable cases entirely disappears. In 5 cases of diabetes with marked constitutional symptoms in which the sugar excretion had been between 7 and 9 per cent., the urine has remained free from sugar for many months, and in all patients treated there has been marked improvement in general health.

Salt-Free Diet in Hyperchlorhydria.—Enriquez and Ambard report recent research which confirms their previous assertions in regard to the benefit from withdrawal of salt when the secretion of gastric juice is excessive and the stomach responds with pain. A salt-free diet has a prompt and marked influence on the excessive secretion; the influence on the pains is not felt so soon. Once established, the effect is durable, the pain subsiding permanently and completely in two or three weeks or at most in five weeks. As soon as the pain has been banished by a strictly salt-free diet, the patient is allowed to have his own salt-cellar to use as desired, the food still prepared without salt. This gives the patient a feeling of freedom which renders the restrictions less irksome, and as the capacity of the salt cellar is known, the exact amount he is taking can be estimated. The patient is also given the liberty to eat the ordinary food when dining out, or at certain intervals. The salt-free diet should be instituted in every case of hyperchlorhydria rebellious to other measures. The vanishing of the pains after withdrawal of salt may also turn the scale in favor of a benign gastric affection in certain dubious cases. The article from which the above is taken appeared in the *Revue de Médecine Interne et de Thérapeutique*, October, 1909.

The Development of the Parasite of Oriental Sore in Cultures.—The parasite causing Oriental sore was first described accurately by Wright and named by him *Helcosoma tropicum.* On account of their obvious affinity with the Leishman-Donovan bodies of kala-azar, Wright's bodies have been referred by subsequent writers to the previously established genus *Leishmania* (Ross), and they now stand as *Leishmania tropica*, the only other known species of the genus being *L. donovani*, the parasite of kala-azar. The Wright bodies were first grown by R. Row (*Quart. Jour. Microsc. Sc.* 1909, liii, 747), who gives the cultural characteristics, a description of the fresh parasite when just taken from the sore, when grown on artificial media and when stained in Giemsa's stain. It was found not to grow in a sterile citrate solution (2 per cent.)—thus differing from the Leishman-Donovan bodies—but did grow well on human blood-serum. "The cultural result is very similar to that obtained for the Leishman-Donovan body. It is of some interest, however, that the method of cultivation required appears to be quite different in the two cases, a fact which indicates that the transmission and mode of development are different in the two parasites." "In smears from the juice of the sore stained in Giemsa's stain the parasites are seen in all sorts of shapes —pear-shaped, oval, torpedo-shaped and even spherical. They are found free outside the corpuscles and also in the large macrophages." In cultures after forty-eight hours the parasite in length is two and one-half to three times the diameter of a red-blood cell and about three times as long as broad. The shape is like a banana; "the contour of the body is well defined, the sides being parallel and the ends rounded"; the anterior extremity bears the micronucleus and the parasite has no power of movement. "At seventy-two hours the development is complete" and the flagellum has formed, which is "one and a half times or twice the length of the body of the parasite, and has from six to eight symmetrical undulations." Once the flagellum is formed, the individual is liberated and is free to swim away from the colony. "In life the flagellum is very active and moves very rapidly with a lashing, wave-like, not a corkscrew-like, movement; in appearance it strongly resembles a spirochete."

The Nerves of the Atrioventricular Bundle.—The location, physiology and microscopic structure of the atrioventricular bundle (the bundle of His), with particular reference to its nerve constituents, are considered by J. Gordon Wilson in a paper (*Proc. Roy. Soc.*, 1909, lxxxi, 151) reporting some of the results of his researches on this bundle. In his historical sketch of our knowledge of the bundle special reference is made to the work of Tawara, who claims that the atrioventricular bundle has a uniform arrangement in all mammals (including man), and the outspreading of the bundle into the atrial and ventricular musculature, respectively, consists of Purkinje fibers or their equivalents. This uniting system is early developed in the embryo. From this time on, leaving growth out of consideration, it remains unchanged during life. It is not affected by hypertrophic and atrophic processes in the heart in the same way as the ordinary cardiac muscle. Wilson finds that "anatomically the atrioventricular bundle contains not only a special form of muscle fiber distinct from the ordinary muscle of the atrium or the ventricle, but it is an important and intricate nerve pathway" in which are found numerous ganglion cells—monopolar, bipolar and multipolar. Abundant nerve fibers run through it in strands and there is an intricate plexus of varicose fibrils around and in close relation to its muscle fibers, also the abundant vascular system well supplied with vasomotor nerves. "Physiologically it has been shown that the atrioventricular band constitutes the pathway which assures the *communication of the atrioventricular rhythm*. When the bundle is sectioned or crushed the ventricles cease momentarily to beat, though they soon regain pulsation, but with a rhythm more slow than that of the atrium. Pathologic anatomy supports this view; the allorhythmia or Stokes-Adams disease can be explained satisfactorily by lesions involving this pathway." It has been very generally held that, this pathway being muscular, the conducting mechanism between the atrium and ventricle must be myogenic. The findings of Wilson are opposed to this hypothesis. "In these experiments and pathologic conditions an important nerve pathway is equally involved with the muscle bundle. Considering the neurogenic as opposed to the myogenic hypothesis from the anatomic standpoint, one must acknowledge that the very complex nerve constituents of the bundle are very suggestive of an intricate nerve mechanism." Finally Wilson discusses the possibility of the atrioventricular bundle being a neuromuscular spindle. The presence of ganglion cells and the absence of those anatomic and neurologic constituents characteristic of the muscle spindle are opposed to a neuromuscular hypothesis.

Uniform Statistics for Puerperal Fever.—P. Rissmann of Osnabrück suggests as a uniform basis for statistics in regard to puerperal fever that the record should include (1) brief record of the birth, date of entry, internal examination, injuries, and operation, if any; (2) temperature above 38.5 C., and date of first fever; (3) pulse over 100; (4) length of stay in the institution; (5) death and autopsy findings, or (6) discharged free from disturbances; or complications, if any; (7) remarks, existing or intercurrent affections, and (8) final outcome; later examination. He gives a specimen chart for the purpose in his communication on the subject in the *Gynaekologische Rundschau*, 1909, iii, 740.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

INJECTIONS OF ALCOHOL FOR FACIAL NEURALGIA

To the Editor:—Please refer me to information regarding the injection of alcohol for relief of facial neuralgia.

F. W. WILCOX, St. Petersburg, Fla.

ANSWER.—The following articles which have appeared in THE JOURNAL will give a fairly complete idea of the subject:

Patrick, H. T.: "Treatment of Trifacial Neuralgia by Means of Deep Injections of Alcohol," Nov. 9, 1907, xlix, 1567.

Patrick, H. T.: Same subject, report of seventy-five cases treated, Dec. 11, 1909 (this issue), liii, 1987.

Hecht, D.: "Methods and Technic of Deep Alcohol Injections for Trifacial Neuralgia," Nov. 9, 1907, xlix, 1574.

"K" PACKAGE

To the Editor:—Please give the contents of the "K" package spoken of in the abstract of Raymond's article in THE JOURNAL, Nov. 20, 1907, liii, 1768.

C. O. HENRY, M.D., Fairmont, W. Va.

ANSWER.—The "K" package originally issued to soldiers at Columbus Barracks for the prevention of venereal disease, contained 2 c.c. of a solution of protargol, 20 parts, glycerin, 20 parts, and distilled water, 60 parts, and a medicine dropper, instructions being given to the soldier to inject this solution immediately after illicit connection. The package now in use contains 4 c.c. of a 25 per cent. solution of argyrol, 4 c.c. of a 30 per cent. calomel ointment, and a medicine dropper.

COLONIES FOR EPILEPTICS

To the Editor:—In what states are there colonies for epileptics?

W. O. BELL, M.D., Seattle, Wash.

ANSWER.—Following are some of the state colonies:

Craig Colony for Epileptics, Sonyea, N. Y.

Hospital Cottages for Children, Baldwinsville, Mass. Hartstein Wendell Page, Medical Superintendent.

New Jersey State Village for Epileptics, Skillman, N. J. David Fairchild Weeks, Medical Superintendent.

Indiana Village for Epileptics, New Castle, Ind. W. C. Van Nuys, Medical Superintendent.

North Carolina has recently opened an epileptic colony in connection with one of her state hospitals for the insane. There are also state institutions of various kinds for the care of epileptics in Ohio, Texas, Pennsylvania, Kansas, Michigan and Minnesota, besides a number of semi-private institutions scattered throughout the country.

THE NEGRI BODIES

To the Editor:—Please tell me where I can find Negri's original article (1903) on the Negri bodies in diagnosis of rabies? E. B.

ANSWER.—Negri published his discovery in the *Zeitschrift für Hygiene und Infectionskrankheit*, xliii, No. 3. An editorial on this subject in THE JOURNAL, Oct. 29, 1904, xliii, 1311, gives a brief account of the technic of investigation and character of *these* bodies. Another article by Negri appears in the periodical first mentioned, xliv, No. 3. These papers may be borrowed from the Surgeon-General's Library at Washington.

The Public Service

Medical Department of the Army

Changes for the week ended Dec. 4, 1909:

Brown, Orville G., capt, granted an extension of 10 days to his leave of absence.

Wales, Philip G., major, relieved from duty at Fort Apache, Ariz., and ordered to the Presido of Monterey, Cal., for duty.

Smith, Allen M., major, relieved from duty at the Presidio of Monterey, Cal., and ordered to Fort Sam Houston, Tex., for duty.

Raymond, Henry I., lieut. col., relieved from duty at Fort Sam Houston, Tex., and ordered to St. Paul, Minn., for duty as chief surgeon, Department of Dakota.

Maus, Louis M., col., relieved from duty as chief surgeon, Department of Dakota, and ordered to Chicago, for duty as chief surgeon, Department of the Lakes.

Byrne, Charles B., col., relieved from duty as chief surgeon, Department of the East; will proceed home at the expiration of his present leave of absence and await retirement from active service.

Blanchard, Robert M., capt., granted sick leave of absence for 2 months.

Ferguson, James B., 1st lieut., M. R. C., granted leave of absence for 4 months.

Barney, Frederick M., 1st lieut., M. R. C., granted leave of absence for 1 month.

Bowman, Madison H., 1st lieut., M. R. C., ordered to Seattle, for temporary duty on the transport *Dix*.

Medical Corps of the Navy

Changes for the week ended Dec. 4, 1909:

Dickson, S. H., medical director, commissioned Medical Director from Oct. 31, 1909.

Fitts, H. B., medical inspector, commissioned Medical Inspector from Oct. 3, 1909.

Jones, E. L., P. A. surgeon, commissioned P. A. Surgeon from Jan. 6, 1909.

Ames, M. H., P. A. surgeon, commissioned P. A. Surgeon from March 24, 1909.

Allen, A. H., P. A. surgeon, commissioned P. A. Surgeon from May 2, 1909.

Furlong, F. M., surgeon, detached from the *Vermont* and ordered home and granted sick leave for 3 months.

Williams, R. B., surgeon, detached from the Navy Yard, Philadelphia, and ordered to duty in connection with the *South Carolina*, and to duty on that vessel when placed in commission.

Grunwell, A. G., surgeon, detached from the *Kansas* and ordered to treatment at the Naval Medical School Hospital, Washington, D. C.

Minter, J. M., asst-surgeon, detached from the Naval Hospital, Norfolk, Va., and ordered to the *Prairie*.

Foster, T. G., asst.-surgeon, ordered to the *Prairie*.

Wheeler, W. M., surgeon, detached from the Navy Yard, New York, N. Y., and ordered to the *Panther*.

Pleadwell, F. L., surgeon, detached from duty as a member of the Naval Examining and Medical Examining Boards, Washington, D. C., and to duty as assistant to the Bureau of Medicine and Surgery.

Shiffert, H. O., surgeon, detached from the *Lancaster* and ordered to the *Vermont*.

Braisted, W. C., surgeon, detached from duty as assistant to the Bureau of Medicine and Surgery and ordered to special temporary duty in the Bureau of Medicine and Surgery.

Hull, H. F., P. A. surgeon, ordered to the Navy Yard, New York.

Association News

NEW MEMBERS

List of new members of the American Medical Association for the month of November, 1909.

ALABAMA

Anderson, E. C., Amiston.
Bell, A. W., Woodlawn.
Caffee, S. R., Avondale.
Collins, J. A., Birmingham.
Constantine, K. W., Birmingham.
Copeland, W. P., Eufaula.
Dowman, C. E., Jr., Birmingham.
Edmondson, J. H., Birmingham.
Levi, I. P., Anniston.
Mann, S. H., Ensley.
May, E. E., Birmingham.
McGehee, W. W., Montgomery.
Moon, E. K., Birmingham.

ARIZONA

Kennedy, R. D., Globe.

CALIFORNIA

Cerf, A. E., San Francisco.
McClelland, J. L., Los Banos.
Reed, J. R., Pasadena.
Wright, T. B., Pasadena.

COLORADO

Farnsworth, J. A., Fort Morgan.
Harvey, Asa, Forbes Junction.
Roberts, Wm., Denver.
Thompson, Virgil, Hotchkiss.

FLORIDA

Lartigue, Etienne, Gainesville.
Lowry, C. S., Jacksonville.
Thompson, T. C., Jacksonville.

GEORGIA

Cone, R. L., Groveland.
Dancy, W. R., Savannah.
Darby, J. I., Columbus.
Dorsey, R. T., Atlanta.
Fox, R. L., Brunswick.
Hilsman, P. L., Albany.
Moncrieff, J. T., Columbus.
Ridley, C. L., Hillsboro.
Russell, E. A., Fitzgerald.
Willis, C. H., Barnesville.

IDAHO

Boeck, L. W., Boise.

ILLINOIS

Anderson, A. L., Aurora.
Atchison, A. B., Rockford.
Best, C. L., Freeport.
Bohan, J. M., Galesburg.
Bothwell, R. S., Batavia.
Campbell, R. L., E. St. Louis.
Clement, C. C., Chicago.
Everett, J. M., DeKalb.
Fouser, G. G., Chicago.
Frazier, F. R., Yorkville.
Gill, G. P., Rockford.
Goembel, E. W., Rockford.
Gordon, E. E., Cairo.
Hanford, F. W., Rockford.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Public Health Campaign in Boston

Mr. E. W. McSweeney of Boston has made a report to Hon. George A. Hibbard, the mayor of Boston, on the question of public health, which appears in the October *Annals of Medical Practice*. After stating that it is undeniable that the health of a community is its best asset and that the campaign against tuberculosis is only one part of the problem, Mr. McSweeney discusses the progress that has been made in antituberculosis work since 1906 and recommends that the governor of Massachusetts and the mayor of Boston join in the appointment of a commission to consider the relations which should exist between the state and the city and to agree on a plan of action which will centralize action, reduce expense and increase results, which will aim at something and get somewhere. He furthermore states that, in his opinion, if a basis of cooperation between the state and the various cities and towns cannot be found, it will be much better for the state to take over the entire control of the consumptive problem and to relieve Boston altogether, rather than to continue the present unbusiness-like methods of work.

Mr. McSweeney's second recommendation is that, following the formulation of a general plan of government, the entire reorganization of the Boston health board will be necessary. He states that for more than a decade this body has been steadily losing ground and that it must be reorganized under a single head, no matter who the man is or whatever may be the cost. Especially interesting is his comment that it is no excuse for Boston to point out that it has only followed the bad example of the United States Government "which cares for health and quarantine matters through the Public Health and Marine-Hospital Service, vital statistics through the Bureau of the Census, pure food through the Department of Agriculture, etc."

Mr. McSweeney therefore recommends that the mayor of Boston address a letter to the president of the United States setting forth that, as the health of the city is the most vital concern of the nation, Boston desires to get in line with the most modern scientific progress in this regard and therefore asks for the loan of a competent physician now in the government service to act as medical adviser to the mayor for a period of two or three years. In this connection he mentions four physicians, officers of the United States Public Health and Marine-Hospital Service, whose work in the last few years has been noteworthy and conspicuous.

Taking up the question of the preservation of the child, he recommends that the school committee be relieved absolutely from responsibility for the medical treatment of the children in the schools, as the problem of tuberculosis and other diseases in the public schools is a health problem and not a school question. He states that the best plan which he has found is that adopted by the London county council, which is about to utilize existing hospitals and institutions for the medical treatment of children, giving financial help if necessary and carefully avoiding pauperizing the pupils. The plan proposes that while children suffering from a specific disease must be cared for, the parent shall have the first opportunity to care for them through the family physician and that when this is not possible the children shall be cared for in the hospitals and clinics established, the cost to be charged to the parent of the child treated unless they are unable to pay, in which case the cost is to be paid out of the city treasury.

The Middleman in Medicine

The secretary of state of New York recently refused to file a certificate of incorporation of a Brooklyn concern organized to supply medical treatment and burial service to its members. The position taken by the secretary of state is important in view of the organization in various parts of the country of so-called "Burial and Aid Societies," which offer policies for a small weekly payment binding the company to furnish free medical and surgical service in case of illness, in many cases free medicines and surgical appliances, as well as funeral expenses in case of death.

The secretary of state has ruled that a corporation cannot practice medicine in New York. The company did not propose to practice medicine and surgery itself, but intended to make contracts with physicians to treat the policy-holders of the company at a nominal rate. The New York courts have decided that a corporation cannot practice law and this decision has operated to the extent of prohibiting a certain company in New York City from supplying its patrons with legal services, a scheme which, it is stated, it had worked up into an established and profitable business. By the same line of reasoning, the purpose of the proposed corporation in New York was simply to act as an agent or a middleman between the policy-holder or patrons on the one side and the physicians and undertakers on the other, the profits of the company to be found in the difference between the amount paid it by the policy-holder and the amount paid out to the doctor or undertaker for services.

This form of contract practice, as brought out in a previous discussion on this subject in The Journal (Dec. 14, 1907), is thoroughly reprehensible, since it amounts practically to buying the services of the physician at wholesale and selling them at retail, the middleman in the form of the exploiting company taking the profit. As was previously pointed out, this form of practice should be condemned, not necessarily because a contract exists for the rendering of services but because the arrangement made is economically unjust and is calculated to work injury to the physician, the patient and the public.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fourth Month—Third Weekly Meeting

Pelvic Cellulitis

Pathology: Modes of extension of infection to cellular tissue. Lymphangitis, phlebitis, perilymphangitis and periphlebitis. Terminations, resolution, chronic cellulitis, suppuration. Involvement of adjacent viscera. Relation of cellulitis and tubal inflammation.

Diagnosis: General symptoms. Location, form, relations, mobility, consistence of inflammatory exudate. Differentiate from pelvic peritonitis, pyosalpinx, pelvic hematocele, appendicitis, psoas abscess.

Salpingitis

Etiology: Abortion, labor, instrumentation, adjacent infections, menstrual congestion, acute exanthemata, distorted tube, etc. Micro-organisms.

Classifications (a) Catarrhal, salpingitis serosa, resulting in sactosalpinx serosa—hydrosalpinx; (b) purulent, salpingitis purulenta, resulting in sactosalpinx purulenta—pyosalpinx; (c) hemorrhage leads to sactosalpinx hemorrhagica—hematosalpinx.

Symptoms and Diagnosis: (a) Gonorrheal, (b) puerperal, (c) tubercular salpingitis.

Ovaritis

Acute and Chronic: Pathology of each. Symptoms and physical signs.

Pelvic Peritonitis

(a) Exudative, (b) adhesive, (c) tubercular, (d) *pachyperitonitis; etiology and pathology of each.* Differentiate pelvic peritonitis from pelvic cellulitis, salpingitis, ovaritis.

Society Proceedings

COMING MEETINGS

American Physiological Society, Washington, D. C., December 28-30.
Medical Society of State of New York, Albany, January 25.
Southern Surg. & Gynecological Assn., Hot Springs, Va., Dec. 14-16.
Western Surgical and Gynecological Assn., Omaha, December 20-21.

AMERICAN ACADEMY OF MEDICINE

Third Mid-Year Meeting, held at New Haven, Conn., Nov. 11-12, 1909

CONFERENCE ON PREVENTION OF INFANT MORTALITY

As a result of the conference arranged by the American Academy of Medicine on prevention of infant mortality, the American Association for Study and Prevention of Infant Mortality was organized at a special meeting called at the close of the conference and held November 13 in Lampson Hall, Yale University. Dr. F. H. Gerrish of Portland, Me., presided, and Dr. Charles McIntire, Easton, Pa., acted as secretary. A constitution and by-laws were adopted and officers elected. These were noted in The Journal, November 20, p. 1751. It was decided that the board of directors should number at least thirty members. The complete number was not appointed, the directorate being authorized to elect additional members at a later meeting. Those appointed included Dr. H. Merriman Steele, Yale Medical School; Dr. Charles Richmond Henderson, professor of sociology of the University of Chicago; Dr. F. H. Gerrish, Portland, Me.; Dr. J. Morton Howell, health officer, Dayton, Ohio; Dr. John M. Connolly, Boston; Dr. H. J. Gerstenberger, Cleveland; Prof. Isabel Bevier, University of Illinois; Dr. W. H. Carmalt, Yale Medical School; Dr. Thomas Morgan Rotch, Harvard Medical School; Prof. Irving Fisher, Yale University, president of the Committee of One Hundred on National Health of the American Association for the Advancement of Science; Dr. Caroline Hedger, of the United Charities, Chicago; Dr. Lilian Welsh, Baltimore; Dr. J. F. Edwards, department of health, Pittsburg, Pa.; Dr. Richard A. Urquhart, Johns Hopkins Medical School, Baltimore; Dr. Charles P. Putnam, Boston; Dr. Thomas Darlington, health commissioner of New York City; and Dr. W. A. Evans, health commissioner of Chicago. Baltimore was selected as the next meeting place of the society. The meeting will be held in the autumn of 1910. Dr. Charles Richmond Henderson of the University of Chicago was nominated president for 1910-1911.

Resolutions Adopted

The task of preventing infant mortality is second to none in importance and should engage the best attention and effort of all individuals, lay and professional, and of every commonwealth and community. As looking toward this., the Academy records its convictions in the following resolutions:

First. *Resolved:* That the present high rate of infant mortality is due to inherited debility or disease, improper environment and care, improper feeding and communicable diseases, and is to a high degree preventable.

Second. *Resolved:* That the breast feeding of infants is, when possible, the only proper method and that artificial feeding should never be substituted as a matter of choice.

Third. *Resolved:* That the reporting of all communicable diseases, especially of those commonest in society, to health boards, should be compulsory.

Fourth. *Resolved:* That the scientific instruction of the young in practical hygiene and sanitation, and of mothers in the care and rearing of infants is an important duty resting chiefly on physicians, sociologists, school authorities and boards of health.

The conference was opened by a brief address of greeting by President Hadley of Yale University. The response was made by Dr. W. Blair Stewart of Atlantic City. There were four sessions. The first, devoted to the medical prevention of infant mortality, was presided over by Dr. J. H. Mason Knox, Jr., Baltimore, and Dr. Richard A. Urquhart, Baltimore, was secretary. The second session was on the philanthropic prevention of infant mortality and Dr. Edward T. Devine, general secretary of the Charity Organization of New York City, and editor of the *Survey*, was chairman, and Miss Lilian Brandt of New York was secretary. Institutional prevention of infant mortality was considered at the third session, which was presided over by Mr. Homer Folks of New York, secretary of the New York State Charities Aid Association, with Miss Mary Vida Clark as secretary. Educational prevention of infant mortality was the subject of the last session, the chairman of which was Prof. C. E. A. Winslow, biologist in chief of the laboratory of sanitary research of the Massachusetts Institute of Technology.

Relation of Alcoholism to Infant Mortality

Dr. J. H. Mason Knox, Jr., Baltimore: The importance of united effort to curtail the long prevailing infant mortality is at last being generally recognized. Physicians should be in the van of this movement because they as a class understand most thoroughly the factors bringing about this large death rate among infants, and know how it can be much diminished. Public sentiment must be aroused to insist on suitable hygienic surroundings, adequate care and proper diet for every new-born babe. The minimum of these requirements must be pointed out by physicians. No field in medicine is more enticing. The potential energy of an infant saved from death by proper medical care and nursing supervision cannot possibly be reckoned. The future of these little lives cannot be foretold as can the lives of adults saved from disease. It behooves us then as physicians to investigate thoroughly all sources of this appalling death rate and to make them known to the public, at the same time suggesting remedies. Among the factors directly and indirectly destructive to the life of infants in this country and in most civilized countries is acute and chronic alcoholism in the parents. The injurious effect of alcohol on the infant is threefold: First, the mother's tissues, nervous system and other organs may be so weakened by taking alcohol as to lower her vitality greatly. Second, the germinal cells of both parents may be more or less injured by the ingestion of large amounts of alcohol. Third, alcohol imbibed in large quantities by the pregnant mother may affect the vitality of the fetus. The disastrous effect of chronic alcoholism on the home and so indirectly on the infant life needs little emphasis in this section.

DISCUSSION

Dr. Thomas Morgan Rotch, Boston: It is well in any consideration of the subject to remember that alcohol is a drug and as such has an important use.

The Relation of Tuberculosis to Infant Mortality

Dr. Clemens von Pirquet, Baltimore: The great frequency of tuberculosis among infants is shown by the records of post-mortem examinations in Berlin, Vienna and New York. The different clinical forms of infantile tuberculosis are described as chronic tuberculosis of the visceral glands (which is often mistaken as a gastrointestinal marasm), chronic tuberculosis of the lungs, caseous pneumonia, and the meningitic and bronchitic forms of miliary tuberculosis. Children infected within the first year of age nearly always die from tuberculosis, whereas in older children the process is often localized. The best prophylaxis would be the entire separation of infants from adults who are likely to be tuberculous, even separation from parents in such a case. As this cannot often be strictly carried out, prophylaxis has to be exercised at least in such a way as to avoid kissing and fondling of children by tuberculous people, and coughing in their presence.

DISCUSSION

Dr. Helen C. Putnam, Providence, R. I.: Does Dr. v. Pirquet consider that there is danger of infection to an infant in a family which moves into a house formerly occupied by a family in which there had been active tuberculosis? How long does such danger, if any, persist, and what amount of cleaning is required to render such a building suitable for occupation?

Dr. Thomas Morgan Rotch, Boston: In antituberculosis work care must be taken not to exclude tuberculous patients from institutions in which they would be benefited and in which they do no harm. There is a hospital in New England which is eminently fitted to receive tuberculous babies and young children, but from which all such were excluded. Finally, acting on my advice, non-infectious cases were admitted. As a result complete cures were effected within three or four months. The medical profession is indebted to

Dr. von Pirquet for his development of the subcutaneous test for tuberculosis, as it has proved to be a means of detecting the disease in an earlier stage than is possible by any other means. Dr. v. Pirquet's work with tuberculin will make his name go down to posterity as one of the great reformers in tuberculin investigations, and as one who has done an immense amount of good to humanity.

Dr. Ward Crampton, New York: Would Dr. v. Pirquet advise the segregation of school children who have reacted positively to the subcutaneous test? One society in New York discovered that 23 per cent. of the children examined responded positively. If an examination of the public school children were to reveal the presence of tuberculosis among an equally large percentage of the children, the problem of separation and segregation would assume very serious proportions.

Dr. von Pirquet: A good cleaning of the whole house, with painting of the walls and fumigation of the rooms would be required to render a building such as described by Dr. Putnam free from infection. It has not yet been proved to what extent children suffering from tuberculosis are sources of infection. I do not consider it necessary to separate the children in a hospital except in the case of those suffering from open lung tuberculosis. I advise the separation of tuberculous children from well children when the test reveals the presence of the disease in an institution such as an orphan asylum, but do not urge the segregation of school children.

Dr. T. M. Rotch: In my opinion, the child who reacts positively should be taken out of school for his own sake, so that he may have outdoor treatment, and not because there is danger of his being a source of infection to others, especially as I do not consider that the danger always exists.

Dr. Guy Kiefer, Detroit: Does Dr. Rotch consider it necessary to distinguish between open and closed cases among school children who react positively to the test and who on that account have been segregated from the rest?

Dr. Rotch: My previous remarks applied only to noninfectious cases; the infectious cases should be isolated just as measles and smallpox are.

The Relation of Mothers' Occupations and Long Hours to Infant Mortality

Dr. Caroline Hedger, of the United Charities of Chicago, cited facts from England, America (colored) and Germany bearing on connection between occupation of married women and infant mortality. She discussed the influences on childbearing and on lactation of beast-of-burden trades, muscular fatigue trades, nervous fatigue trades, and poisonous trades, and enumerated desirable modifications in these trades with respect to hours, sanitation, time-limit before and after confinement. Dr. Hedger then took up the secondary effects on infant mortality of married women at work: wages, drink, drugging, homes and abortion.

She then went on to say: Women are in industry to stay. William Hard says: We cannot tomorrow dismiss 6,000,000. We must (1) find out the effect of factory work on women by laboratories, enumeration, birth statistics; (2) so arrange labor that (a) the woman can work without losing her chance of normal motherhood, including lactation; (b) develop day-nurseries; (c) use them as laboratories for teaching infant feeding; (d) always tend toward a wage that will permit those who wish to remain at home.

DISCUSSION

Mr. Edward Bunnell Phelps, New York, editor the *American Underwriter*, gave the statistics he had collected in an investigation which covered 14 textile manufacturing cities, of the relation of woman's work to infant mortality. These figures indicate that the infant mortality rate varies as does the percentage of working women of child-bearing age. This state of affairs is not confined to this country as, according to statistics representing eight leading textile towns in England from 1896 to 1905, the infant mortality rate is 182, while the normal rate for other towns is 147. In France, in textile towns, the rate was found to be 196, and in other cities 140; in German textile towns, 266; in other towns, 207. In the United States, the average in textile towns was 183, as against 145 for the registration area. According to the census of 1900 there were a trifle more than 1,000,000 women, sixteen years old and over, working in factories; their average earnings were a little less than 90 cents a day. In view of the inability of the mothers to care for their children themselves, or to provide healthful surroundings for their children, he advocated the establishment of some form of day nursery.

The Relation of Diet to Infant Mortality

Dr. J. P. Crozer Griffith, Philadelphia: The excessive mortality of early life occurs principally in artificially fed children and is due chiefly to diarrheal disturbances. The mortality can be largely prevented by breast feeding. There are difficulties in obtaining a suitable artificial food. Many reasons are assigned for weaning, but there is an apparently increasing desire of mothers to nurse their children. Artificial feeding increases mortality.

DISCUSSION

Mr. Hastings Hart, the Sage Foundation, New York: In the case of illegitimate children, the main obstacle in the way of maternal nursing has been the practice of physicians and nurses in maternity hospitals of advising the mother not to nurse the child on the ground that they would have to be separated eventually, and the mother would become too much attached to the child if she nursed it.

Dr. Woods Hutchinson, New York: Artificial foods of any sort are to be condemned. Mortality is least among the breast-fed infants; the percentage is 3 times greater among those fed on cow's milk; and still greater among those fed on artificial foods. I hope to see the time when the manufacture, advertising and sale of mixtures ostensibly for babies, but really for the profit of the manufacturers, will be a misdemeanor punishable by fine and imprisonment.

Dr. Ira S. Wile, New York: The responsibility for the proper feeding of infants rests on physicians, and goes back ultimately to the medical schools which should give more adequate instruction in pediatrics before turning its graduates loose on an innocent and unsuspecting public.

Dr. Lilian Welsh, Baltimore: It is not a question of physicians in some places, but of midwives.

Dr. Thelberg, Vassar College, advocated thorough physiological instruction of the students in women's colleges and in girl's schools.

Dr. Herman Schwarz, New York: The reduction of infant mortality could be accomplished by the combination of three methods: the care of the child before, during and for at least a year after birth; the education of parents; encouragement of breast feeding and securing pure milk for infants who have to be bottle fed. Breast feeding will reduce the great mortality from gastroenteritis.

(To be continued)

Marriages

Edgar Clay Doyle, M.D., to Miss Mary Cherry, both of Seneca, S. C., September 16.

Chester E. Kinzel, M.D., to Miss Elsie Bailey, both of Wilmington, Ohio, November 17.

Cleland G. Moore, M.D., North Bend, Neb., to Miss Emma G. Lewis, of Baltimore, October 5.

Harry M. Hosmer, M.D., Gary, Ind., to Miss Helen Barton, of Kansas City, Mo., November 23.

Albert Havens, M.D., to Miss Gertrude Crabtree, both of New Philadelphia, Ill., November 20.

Harry Waldemar Boice, M.D., to Miss Fannie Elizabeth Glassey, both of Brooklyn, November 24.

Preston G. Hundley, M.D., of West Virginia, to Miss Mary E. Lyell, at Baltimore, Md., November 24.

John F. O. Howell, M.D., Skidmore, Texas, to Miss Wila Williams, of Hickman Mills, Mo., recently.

Charles R. Sheridan, M.D., Maysville, Ky., to Miss Helen Carney of Wheeling, W. Va., November 30.

James R. Maxfield, M.D., Grand Saline, Texas, to Miss Marie Streeter, of Waco, Texas, September 29.

Richard Phillips Bell, M.D., Chattanooga, Tenn., to Miss Mary Grasty, at Staunton, Va., November 24.

Deaths

Alfred D. Kohn, M.D. Rush Medical College, Chicago, 1898; a member of the American Medical Association; in 1907 and 1908 a member of the Chicago Board of Education; assistant in medicine in Rush Medical College; chief of the clinic on gastrointestinal diseases at the United Hebrew Dispensaries; attending physician to Michael Reese Hospital; a specialist on diseases of the stomach and intestines; died in the Michael Reese Hospital, December 2, from cerebral hemorrhage, eight days after an operation for appendicitis, aged 40.

Isaac Newton Snively, M.D. Bellevue Hospital Medical College, New York City, 1889; a member of the American Medical Association, and a fellow of the American Academy of Medicine; professor of materia medica, therapeutics and clinical medicine, and dean of Temple College of Philadelphia; visiting physician to the Garrettson and Samaritan hospitals; died in the latter institution, November 23, from pulmonary thrombosis, following an operation for carcinoma of the colon, aged 45.

William Henry McKelvey, M.D. College of Physicians and Surgeons, New York City, 1866; a member of the American Medical Association; for 37 years a member of the Pittsburg Board of Education; for 34 years a member of the Central Board of Education, and for 20 years its president; physician to the Allegheny county jail from 1868 to 1881; and for 30 years a member of the city council; died at the home of his brother, in Pittsburg, November 23, aged 66.

Donald Churchill, M.D. Harvard Medical School, Boston, 1899; a member of the American Medical Association and American Academy of Medicine; secretary of the Providence (R. I.) Medical Association and treasurer of the Rhode Island Hospital Club; admitting physician to the Providence Lying-In Hospital; and surgeon on the staff of the Rhode Island Hospital; died at his home in Providence, November 23, from septicemia, following an operation wound, aged 39.

Harry Martyn Acheson, M.D. University of Pennsylvania, Philadelphia, 1880; of Washington, Pa.; a member of the American Medical Association; for several terms president of the Washington County (Pa.) Medical Society, and the Washington Academy of Medicine; one of the organizers of the Washington Board of Health, and for many years its president; died in St. Francis Hospital, Pittsburg, November 29, from general nervous breakdown, aged 51.

Albert M. Smith, M.D. Jefferson Medical College, Philadelphia, 1870; a member of the American Medical Association; twice a member of the Pennsylvania legislature; a veteran of the Civil War; for 29 years local surgeon of the Pennsylvania System; a member of the local pension board of Beaver Springs; and vice-president and director of the Beavertown Mutual Fire Insurance Company; died at his home in Beaver Springs, November 22, aged 65.

Richard Watson Fry, M.D. University of Virginia, Charlottesville, 1872; College of Physicians and Surgeons, New York City, 1873; a member of the Medical Society of Virginia; of Roanoke, Va.; local surgeon to the Norfolk and Western Railroad; for several years city physician and president of the Board of Health of Roanoke; died in the Jefferson Hospital in that city, November 22, after an operation for prostatitis, aged 59.

John Samuel Cooper, M.D. Georgetown University, Washington, D.C., 1868; of Louisville, Ky.; from 1868 to 1880 a surgeon in the army; later special agent for the quartermaster's department, U. S. Army, and an officer of the revenue service; died in the Norton Infirmary, Louisville, November 25, from peritonitis, following an operation for disease of the bladder, aged 66.

Samuel Kohn, M.D. New York University, New York City, 1877; formerly president of the Sanitarium for Hebrew Children, Rockaway Park; one of the founders and chief of the laryngologic, otologic and rhinologic departments of the German Polyclinic; died at his home in New York City, November 26, from chronic nephritis, aged 55.

John W. Slade, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1857; surgeon of the Eleventh Missouri Volunteer Infantry during the Civil War; for several years a member of the State Board of Medical Examiners of Oklahoma; died in his apartments in Guthrie, November 26, from senile debility, aged 83.

Jacob Quick, M.D. University of Pennsylvania, Philadelphia, 1851; surgeon of the Twenty-second New Jersey Volunteer Infantry during the Civil War; for a time a member of the staff of the German Hospital, Philadelphia; died at the home of his son in West Philadelphia, November 20, from senile debility, aged 83.

John Charles Shearer, M.D. State University of Iowa, Iowa City, 1896; a member of the Iowa State Medical Society; formerly of Tipton and Allison, Iowa; died at the home of his mother in Lehigh, November 18, from the effects of carbolic acid, self-administered, it is believed, with suicidal intent, aged 35.

Henry Morton Mixer, M.D. Berkshire Medical College, Pittsfield, Mass., 1854; assistant surgeon in the U. S. Navy during the Civil War; afterward a resident of New Hampton, Iowa, and since 1896 a practitioner of Neosho; died at his home in that city, November 23, from senile debility, aged 81.

Hiram A. Wright, M.D. Victoria College, Coburg, Ont., 1885; L.R.C.P., London, 1886; a member of the Michigan State Medical Society; an alienist and medical superintendent of the Pennsylvania Avenue Sanitarium, Detroit; died at his home in that city, November 24, from typhoid fever, aged 46.

William Geoghan, M.D. Albany (N. Y.) Medical College, 1873; a member of the Medical Society of the State of New York; one of the staff physicians of the Metropolitan Life Insurance Company; died suddenly at his home in New York City, November 27, from heart disease, aged 57.

John Barr, M.D. Victoria College, Cobourg, Ont., 1866; of Shelburne; for three terms a member of the Ontario legislature from Dufferin, and for two terms a member of the Dominion Parliament; was found dead in his bed in Ottawa, Ont., November 19, from heart disease, aged 66.

George Emil Voigt, M.D. University of Pennsylvania, Philadelphia, 1901; formerly coroner of Wayne county, Pa.; physician to the county jail and almshouse, and secretary of the Honesdale Medical Society; died at his home in that city, November 29, from uremia, aged 29.

Harlow James Boyd, M.D. Columbus (Ohio) Medical College, 1879; a member of the American Medical Association, and one of the most prominent practitioners of northern Minnesota; died suddenly at his home in Alexandria, November 21, from cerebral hemorrhage, aged 57.

William Samuel Howard, M.D. Medical College of Indiana, Indianapolis, 1892; L.R.C.S., L.R.C.P., Edinburgh, 1893; a member of the Roberts county (S. D.) board of health, and county physician; died at his home in Sisseton, November 19, from heart disease, aged 37.

Henri Theophile Fontaine, M.D. Harvard Medical School, Boston, 1894; a member of the New Hampshire Medical Society; physician in charge of the Pembroke (N. H.) Sanatorium since 1902; died in that institution, November 27, from tuberculosis, aged 42.

Benjamin Robert Bryant, M.D. College of Physicians and Surgeons, Baltimore, 1881; for two terms a representative in the House of Delegates from Southampton county, Va.; died at his home in Boykins, November 14, from pernicious anemia, aged 51.

Virginius Randolph Moss, M.D. Medical College of Virginia, Richmond, 1865; a member of the American Medical Association; for many years a practitioner of Barboursville, W. Va.; died in Moundsville, W. Va., recently, from senile debility.

Burr Schermerhorn, M.D. College of Physicians and Surgeons, New York City, 1863; a member of the local pension board and health officer of Honesdale, Pa.; died at his home in that place, November 25, from heart disease, aged 70.

George H. Aldrich, M.D. Tuft's Medical College, Boston, 1907; formerly house physician to the Waltham Hospital; and later a practitioner of Ludlow, Mass.; died in the Ludlow Hospital, November 22, from typhoid fever, aged 27.

May Burton Collins, M.D. Jefferson Medical College, Philadelphia, 1860; of Glasgow, Mo.; died at the home of his daughter in Kansas City, Mo., November 20, from skull fracture, due to a fall from a street car, aged 72.

Charles C. Van Kirk, M.D. Starling Medical College, Columbus, Ohio, 1897; a surgeon in the United States Indian Service; died at the Leech Lake Agency, Onigum, Minn., November 5, from spinal meningitis, aged 39.

Harvey Mitchell (license, Ind., 1897, years of practice); for 59 years a practitioner of Delaware county, Ind.; and since 1854, of Muncie; died at the home of his daughter in that city, November 22, aged 83.

Lewis Edgar Klinefelter, M.D. College of Physicians and Surgeons, Chicago, 1903; a member of the American Medical Association; died at his home in Rockford, Iowa, November 26, from typhoid fever, aged 32.

Albert R. Lash, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1881; a member of the American Medical Association; died at his home in Ellinwood, Kan., October 10, from cerebral hemorrhage, aged 66.

William H. McGuire, M.D. Eclectic Medical Institute, Cincinnati, 1874; a member of the Indiana State Medical Association; pension examiner; died at his home in Frankfort, November 27, from cerebral hemorrhage, aged 62.

Joseph Marion Lanham, M.D. University of Tennessee, Nashville, 1882; a member of the South Carolina Medical Association; died at his home near Woodruff, November 25, from cerebral hemorrhage, aged 48.

Aden Thomas K. Lynch, M.D. Kentucky School of Medicine, Louisville, 1893; a member of the Kentucky State Medical Association; died at his home in Short Creek, November 22, from typhoid fever, aged 45.

John C. Mahorney, M.D. Hahnemann Medical College, Philadelphia, 1878; was kicked in the abdomen by a horse, near his home in Ladoga, Ind., August 10, and died two days later from his injuries, aged 57.

Josephine E. McKenzie Roberts, M.D. Hering Medical College, 1897; assistant to the chair of diseases of women in that institution; died at her home in Chicago, November 8, from angina pectoris, aged 59.

Frederick William Fisher, M.D. Detroit (Mich.) College of Medicine, 1894; a well-known marine surgeon of Ashtabula, Ohio; died at his home in that city, November 25, from typhoid fever, aged 38.

Heber R. Elderkin, M.D. University of Louisville (Ky.), 1858; a member of the Idaho State Medical Association; was found dead in his office in Coeur d'Alene, November 18, from heart disease, aged 78.

James S. Knox, M.D. Louisville (Ky.) Medical College, 1882; while preparing to make a professional call, died suddenly in his barn at Pellville, Ky., November 20, from heart disease, aged 49.

Esther Hayes Young, M.D. University of Minnesota, College of Homeopathic Medicine, Minneapolis, 1893; of Minneapolis; died in the Asbury Hospital in that city, November 15, from cancer, aged 63.

Frank Kiefer, M.D. Texas Medical College, Galveston, 1867; of Roby, Texas; for 40 years a clergyman; died in the Hollis Sanitarium, Abilene, November 25, from cerebral hemorrhage, aged 76.

Chads D. Chalfant, M.D. Western Reserve University, Cleveland, Ohio, 1886; a member of the Illinois State Medical Society; died at his home in Streator, November 22, from diabetes.

Frederick W. Bates, M.D. Baylor University, Dallas, Texas, 1904; of Dallas; died in the Baptist Sanitarium in that city, November 20, after an operation for appendicitis, aged 29.

Robert Griffis, M.D. Medical College of Ohio, Cincinnati, 1853; for 56 years a practitioner of Middletown, Ind.; died at his home, November 18, from cerebral hemorrhage, aged 83.

Samuel James Kelly, M.D. Laval University, Montreal, 1879; for three terms a member of the common council of Fall River, Mass.; died November 15, from diabetes, aged 53.

Charles Fuller, M.D. Medical School of Maine, Brunswick, 1869; formerly of Lincoln, Maine; died at his home in Dorchester, Boston, November 22, aged 69.

A. R. McFadyen, M.D. Jefferson Medical College, Philadelphia, 1859; died at his home in Jackson Springs, N. C., November 18, from paralysis, aged 78.

Raymond Sauvage, M.D. Tulane University, New Orleans, 1879; died at his home in New Orleans, November 20, from cerebral hemorrhage, aged 66.

Charles F. W. Hall, M.D. Jefferson Medical College, Philadelphia, 1875; died at his home in Parksley, Va., November 14, from cerebral hemorrhage.

Edmund A. Crain (license, Mont., 27 years practice, 1889); died in his apartment in Butte, November 26, from an overdose of morphin, aged 56.

William J. Barron, M.D. Tulane University, New Orleans, 1859; died at his home between Ackerman and Sturgis, Miss., November 22, aged 75.

Edward N. Franklin, M.D. University of Pennsylvania, Philadelphia, 1869; died at his home in Gallatin, Tenn., November 21, aged 64.

Stephen Jack Welsh, M.D. New York University, New York City, 1882; died at his home in Monroe, N. C., November 19, aged 55.

George H. Schmitt, M.D. Detroit (Mich.) Medical College, 1881; died at his home in Los Angeles, November 24, aged 62.

Charles Cook Winslow (license, N. C., 1889); died at his home in Hartford, November 9, from locomotor ataxia, aged 52.

Book Notices

Modern Problems in Psychiatry. By Ernesto Lugaro, Professor of Neuropathology and Psychiatry in the University of Modena. Translated by David Orr, M.D., and R. G. Rows, M.D Publications of the University of Manchester, Medical Series, No. XII. Cloth. Pp. 305, with illustrations. Price 7 shillings 6 pence net. Manchester: University Press (Sherratt and Hughes), 1909.

The purpose of this book is to indicate the lines along which efforts should be made at the present time to solve the many difficult problems of psychiatry. We commend its study to every one who has, in any way, the care of the insane. It is in no sense a text-book wherein one may find cut-and-dried classifications and clinical descriptions to enable one to label particular cases that may fall under observation, but rather a series of essays logically connected and abounding in modern scientific data and philosophical discussion. Hypotheses naturally bristle throughout the book, for the author recognizes the oft-forgotten truth that "every particular cognition is a hypothesis, which, with an increase of experience, can acquire a greater degree of probability but which can never attain to absolute certainty" (p. 55). To the student of psychiatry Lugaro's work will prove to be more helpful and practical than nine-tenths of the text-book compilations with their confusing schemes of classification, ancient psychology, and unconfirmed clinical data. The body of the work consists of seven chapters. The general introduction rivets the attention at once.

Of modern psychiatry Lugaro affirms that "the general tendency which to-day is becoming increasingly stronger, aims at interpreting all mental disturbance as a pathologic manifestation, and welding psychiatry with general clinical medicine" (p. 17). We are cautioned not to "look on normal psychiatry as a purely introspective analysis" (p. 19); but to remember that "in no science do so many sciences dovetail into each other as in psychiatry" (p. 25). Indeed, the dominant tone of of the book, so clearly sounded in this introductory chapter, is that "the alienist must—as much as the time at his disposal and his individual capacity permit—take an active part in work developing in neighboring fields of research, cultivate other sciences, and help them to progress, in order to further the progress of his own" (p. 55); a truth which John Fiske long ago intimated when he asserted that psychology, in its broadest sense, was the science of sciences because the validity of every scientific observation and deduction must rest ultimately on the validity and reliability of the phenomena of mind.

Determination, realism and idealism, and other metaphysical questions are all critically passed in review in Chapter 2 and are more or less dismissed with the statement, "We reject as illusory all these traditional solutions and we deny the legitimacy of the metphysical problem" (p. 39). Anatomy and physiology are regarded with more hope for the elucidation of mentalization.

The neuron doctrine is the ground whereon the "anatomic problems" of the third chapter are worked out. Of this much-debated doctrine the author says, "For a short period it seemed as though it might be shaken from its foundations; but this was merely transitory; criticism stimulated a multitude of researches, and it can now be asserted that the neuron doctrine has successfully resisted all the attacks made on it" (p. 90). In this same chapter are brief but comprehensive discussions of neurotropism, the neurofibrils, and the neuroglia in their functional relationship to mental phenomena.

With Chapter 4, on pathogenesis, we plunge at once into the practical problems of clinical psychiatry, and continued wrestling with them throughout the rest of the book. The rôle of the intoxications and infections, that of exhaustion, those of congenital deficiencies, and of psychic and hereditary factors in the production of mental alienation are admirably presented. The author deprecates the great stress so often laid on the psychic causes. "Even the forms of insanity which are considered to be most easily influenced, if not determined, by psychic causes, may arise independently and without the slightest participation of any psychic disturbance" (p. 184). The analysis of the hereditary factor is profoundly learned and thoughtful. In view of the oft-reiterated commonplaces as to the relationship of heredity to degeneracy, it is highly refreshing to read that "heredity, if it comes into play at all, acts in a direction which is distinctly opposed to degeneration. . . . Degeneration is a disease of the stock, but it is a disease that is curable. . . . The mechanism of hereditary transmission—contrary to the biblical legend—is free from every blemish. It tends to transmit unaltered the products of biologic experience and the adaptations which have been acquired throughout the whole of the evolution of life. External influences alone are capable of disturbing it or of giving rise to disease" (p. 212).

As a final illustration of the author's fearless independence and keenness of reasoning, we note the study, in Chapter 5, of the nasologic problems. No mere hack-writer or text-book compiler would have dared to say, in face of the almost universally contrary practice, that "it would be vain to seek for distinctions based on psychologic observation alone. We should fall into the old errors of mistaking simple psychic syndromes for true diseases and of failing to recognize the close affinity of origin and mechanism which exists between the most diverse syndromes" (p. 253).

Such is this most thought-stimulating and broadly scientific book. We have deemed it best to show the high plane of scientific inquiry which it touches by quoting liberally from its pages. And we earnestly commend its careful perusal by every medical man who is interested in psychiatric problems and who sincerely wishes to become acquainted with the latest advances in this difficult yet fascinating branch of medicine.

Leucopathies, Métastases, Albuminuries et Icteres Leucopathiques. Par Emile Feuillié, Préparateur à la Faculté de Médecine. Paper. Pp. 196, with illustrations. Price, 6 francs. Paris: G. Steinheil, 1909.

This monograph, the result, according to the author's statements, of seventeen years of investigation, bestows on the leucocyte a much more independent rôle than is commonly conceded to it. The conception of a "leucopathy," i. e., of primary modifications in the activities of the leucocytes (secretion, motility, organ infiltration, etc.) is created and a new nomenclature invented that is intended to express these special perversions. The introduction of many new terms and of the hypothetical pathologic conceptions they are meant to illustrate renders the understanding of the volume difficult. The author speaks an unfamiliar language; his disquisition may contain a valuable diamond of truth, but it is very much obscured by the setting given to it. It seems a pity that the nomenclature should be so involved; it prejudices the reader against the value of the statements made. What is true and what is new, could surely be expressed in simple language, readily understood by any one familiar with the ordinary terminology of the pathology of the blood. Of the many heterodox statements enunciated, the following may be selected as types: "In acute nephritis the lesion of the 'noble element' does not produce leucocytic infiltration. If infiltration is present it is due to a coexisting 'leucosis.'" "Cell casts in the urine are an indication of a leucopathy and not of a nephritis." "Edema may coexist with albuminuria; both are simultaneous effects of the same leucopathy." Much is said of nephrosis, nephrexosis and exonephrosis, of leucoxosis and exoleucosis and of leucopathic fibrosis, but it is all obscure. The pamphlet is offered as an incomplete thesis; and the writer naively states, "My master, Bouchard, has advised me to be brief in order to be clear." This is good advice, but it has not been followed. It is to be hoped that at some future day Dr. Feuillié will furnish a brief, clear and comprehensive exposition of this subject in order that more ample justice may be done his diligent labors by the ordinary reader.

Tufts Medical Diet Charts. (Charts A and B.) Prepared by H. D. Arnold, M. D., Professor of Clinical Medicine at Tufts Medical College, Boston. Single Charts, 5 cents; 50 Charts, $2; 500 Charts, $18; 1,000 Charts, $30. Philadelphia: W. B. Saunders Co., 1909.

These are conveniently arranged charts for indicating and calculating the value of the diet. Chart A has space for recording the diet for five successive days or for five changes of diet for any interval of time. Chart B fulfils the same function for a single day. The nutritive value of the food is given for such measures as are used in every-day life. The charts will prove of very practical value for those who give any thought to diet in the treatment of disease.

Chemical and Microscopical Diagnosis. By Francis Carter Wood, M.D., Professor of Clinical Pathology, College of Physicians and Surgeons, Columbia University, New York. Second Edition. Cloth. Pp. 725, with 192 illustrations and 9 colored plates. Price, $5. New York: D. Appleton & Co.

In this second edition of his well-known book, the author has kept his text clear and concise and has eliminated many tests which have proved less accurate and valuable than those inserted in their place. Additional matter has been introduced on some of the new methods for determining the functional activity of the gastro-intestinal tract, especially noticeable being the desmoid reaction of Sahli and the nucleus test of Schmidt. In the chapter on the blood, few insertions are found and, indeed, few were needed, as this section was exceptionally complete in the first edition. The discussion of the *Spirochæta pallida* is, perhaps, somewhat limited, although it is becoming more and more probable that this organism may be only incidentally associated with syphilis. It is unfortunate that Wood has made no mention of the work of Ricketts on the causation and spread of Rocky Mountain fever, as this is not only of great interest but is of extreme importance.

The introduction, into the section on urine, of Folin's methods for the determination of ammonia and of creatinin, as well as of various new and more reliable methods for the determination of beta-oxybutyric acid, has greatly enhanced the working value of this portion of the book. It would, however, seem that the author should have taken the opportunity in this revision to enlarge greatly his clinical discussions of the various factors, which may be closely studied in the urinary output.

It is in the section on transudates and exudates that one observes the greatest changes. Here one finds a discussion of Cammidge's reaction C, of the cutaneous and ocular tuberculin reactions, of the opsonic index, of the Wassermann and hemolytic tests, and a treatment of the Negri bodies as associated with rabies as well as of the Leishman-Donovan bodies as related to kala-azar. These insertions are treated clearly, although somewhat briefly; they should, however, prove of great value to the general as well as to the special student.

This work is to be especially commended for the clearness and brevity of its text, for its careful and judicious selection and discussion of the tests and methods advocated, and for its thorough treatment of the general subject matter of chemical and microscopic diagnosis. The cuts and plates are satisfactory and entirely adequate. A complete index makes the book a very easy one with which to work.

Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition. Part VIII. Gout. By Prof. Dr. H. Strauss, Professor of the Third Clinic, Royal Charity Hospital, Berlin. Authorized American Edition. Translated Under the Direction of Nellis Barnes Foster, M.D., Associate Physician to the New York Hospital. Cloth. Pp. 70. Price, $1. New York: E. B. Treat & Co., 1909.

This little volume is the authorized American translation of a series of articles published seven years ago. They are written altogether for the general practitioner and make no claims to exhaustiveness. The chapters on the pathogenesis of gout, including the pathology and chemistry of uric acid, are clear and concise and contain all the information practically necessary. As was to be expected, particular importance is given to German publications, while the valuable American contributions to this subject are altogether omitted. The symptomatology of uricacidemia is covered in about two hundred words occupying one page. This brevity is commendable, especially by contrast with the voluminous, vague symptomatology covering many pages in other monographs on the subject. There are really very few clean-cut definite symptoms of uric acid intoxication.

The therapeutics of gout are very well presented in this work, especially from the dietetic standpoint. Much that is here recommended apodictically seems rather theoretical and commands consideration chiefly because it is supported by the authority of so careful and experienced a clinician as the author of this monograph. There is nothing new about the treatment of the acute attacks, or about the balneologic management of gouty cases. A great deal of conservatism is displayed in the recommendation of the protean array of drugs that have at different times been recommended for the treatment of gouty manifestations.

Semmelweis, His Life and His Doctrine. By Sir William J. Sinclair, M.A., M.D., Professor of Obstetrics and Gynecology in the University of Manchester. Cloth. Pp. 369. Price, 7 shillings 6 pence. Manchester: At the University Press, 1909.

With the exception of a small monograph written by Dr. Duka, a Hungarian, and published in 1888, this is the first biography of Semmelweis in the English language. This remarkable man, perhaps the only medical discoverer who can be ranked with Jenner in regard to the importance of his discovery, has a life-history as sad as it is interesting and instructive. Professor Sinclair has succeeded in giving a very interesting picture of the man and of the condition of obstetrical practice and teaching of his time, and in conveying a clear impression of the contents of his epoch-making and immortal work, "The Etiology, the Nature and the Prophylaxis of Childbed Fever." In drawing this picture Sinclair has quoted largely from all the chief physicians of Austria, Germany, France, England, Italy and other European and foreign countries, as well as from the work of Semmelweis himself. In this way we get impressive and fascinating details drawn by contemporary hands of a struggle for the acknowledgment of a truth.

The book is divided into nine chapters, the first two of which contain the introduction and a brief sketch of Semmelweis' parentage and nationality. Chapters 3 and 4 describe his life in Vienna, and the rise and spread of the doctrine of the contagiousness of puerperal fever, the disappointment of Semmelweis on account of his treatment, and his departure from Austria. Chapter 5 contains an account of the beginning of his work in Budapest and the further diffusion of his theory before the appearance of his book. In Chapter 6 there is a short but satisfactory abstract of Semmelweis' book, together with a review of his correspondence and an account of the further dissemination of his teachings. Chapter 7 gives an account of his last illness and a summary of the spread of Semmelweis' doctrine. In Chapter 8 the work of forerunners and contemporaries is reviewed and the claims of Holmes considered. While admitting the services of Holmes, Sinclair holds that the work of Semmelweis and that of Holmes are not to be compared. One made a discovery and founded a doctrine; the other did not contribute a fact of his own, but conferred great benefits on humanity by devoting his literary genius to attracting attention to puerperal fever and by trying to suppress the practices which brought childbed fever in their train. Sinclair says, "If Semmelweis could have written like Holmes his 'Etiology' would have conquered Europe in twelve months." In Chapter 9 the relations of the doctrine of the contagiousness of puerperal fever to bacteriology are discussed.

The book closes most appropriately with the eloquent sentiment of his sympathetic biographer, Bruck of Budapest:

"The great revolution of modern times, in obstetrics as well as in surgery, is the result of the one idea that, complete and clear, first arose in the mind of Semmelweis and was embodied in the practice of which he was the pioneer. When we with just satisfaction contemplate and enjoy the achievements which with mighty strides bring us nearer to the Fortune's crowning slope of full fruition, every time must the name of Semmelweis be uttered with grateful recognition."

Clinical Treatises on the Symptomatology and Diagnosis of Disorders of Respiration and Circulation. By Prof. Edmund Von Neusser, M.D., Professor of the Second Medical Clinic, Vienna. Authorized English Translation by Andrew MacFarlane, M.D., Professor of Medical Jurisprudence and Physical Diagnosis. Part III. Angina Pectoris. Cloth. Pp. 71. Price, $1. New York: E. B. Treat & Co., 1909.

This monograph has been a recognized classic for a number of years. In so far as nothing new has been contributed either to the pathogenesis, the diagnosis or the treatment of angina pectoris since this treatise was written, the present English version fulfils a useful purpose. The translation is fairly good. It does not obscure nor does it embellish. The differentiation by type of case-reports from the text proper is omitted in the English edition, probably in order to make a larger volume.

A Book of Quatrains, Original and Translated. By Frederic Rowland Marvin. Cloth. Pp. 101. Price, $1. Boston: Sherman, French & Co., 1909.

This little book is a compilation of original and translated quatrains, many of which are classical. It furnishes pleasant reading for a leisure hour.

Medicolegal

Company Maintaining Hospital Not Liable for Surgeon's Failure to Give Promised Notice of Changed Condition of Patient

The Court of Civil Appeals of Texas says that the case of Carroll vs. St. Louis Southwestern Railway Co. (120 S. W. R. 1079) was founded on the alleged failure of the chief surgeon in charge of the defendant company's hospital to comply with a promise he had made to notify the plaintiff of any unfavorable change in the condition of her son, as a result of a surgical operation he was to undergo for appendicitis.

Admitting all that was alleged—that the promise was given, and that the surgeon either wilfully or negligently failed to send the notice—the court does not think it followed that the railway company would be liable for the consequences of such failure. Before the company could be held responsible it must appear from the averments of the petition, at least, that it owed the duty of sending that notice to the plaintiff when the conditions arose calling for such information. The right to recover damages must depend on the breach of some duty assumed by contract, or imposed by the law of the land. It was claimed only that the surgeon made a promise, without alleging anything which would, in law, constitute a consideration giving to such a promise the force of a binding contract to perform the particular service. There was nothing to show that this promise was more than a personal and gratuitous undertaking on the part of the surgeon to accommodate an anxious mother. But, assuming that it was personally binding on him, there was nothing alleged which would show that he had authority to bind the company by any such promise.

The petition showed that the defendant was an ordinary railway corporation engaged in the business for which such companies are usually chartered. It maintained a hospital for the benefit of its sick and disabled employees, and had placed the surgeon in charge for the purpose of treating the inmates. Certainly, it could not be contended, with any show of reason, that this surgeon had the authority to make binding engagements to transmit to outsiders having no connection with that institution messages regarding the condition of the inmates.

From the facts stated, the only dereliction on the part of the railway company for which the plaintiff might have maintained an action for damages would be such negligence as might have caused the death of her son. But nothing of this character was charged.

If this action be regarded as one founded on the negligent failure to perform a legal duty, as distinguished from a breach of contract, the petition still failed to state any elements of damages recoverable in such a suit. No physical or personal injury was alleged, but mental anguish alone constituted the damages claimed. The doctrine laid down in the telegraph cases, and relied on by the plaintiff as sustaining her right to recover for mental anguish alone, distinctly places their holding on the ground of a breach of contract.

Admissibility of Hospital Records as Evidence

The Supreme Judicial Court of Massachusetts applies, in the personal injury case of Delaney vs. Framingham Gas Fuel and Power Co. (88 N. E. R. 773), to hospital records, practically the same rules which it has applied to tradesmen's books, to determine their admissibility in evidence. The hospital records in question, it says, were not made in accordance with a requirement of law and therefore were not legal records within the meaning of the rule that legal records or copies thereof are generally admissible in evidence. Still it appeared that the hospital records were made in the usual course of business, by a person in the discharge of a duty, who appeared not only as the maker of them, but as their custodian. If she had died and her handwriting had been proved, in the absence of any other testimony as to the manner in which they were made up, they would have been admissible in evidence. It would have been assumed that the records were of facts known to her. The rule or requirement applicable to such records ordinarily is that the entries were made by a person who had personal knowledge of the truthfulness of the statements. That rule or requirement has been adhered to quite generally, except where in the course of the business the clerk making the entry received his information either orally or in writing from various persons whom he cannot expect to remember and whom it will be impracticable to call as witnesses.

But in this case it appeared that the person who made the records and had the custody of them, never had any personal knowledge of the facts stated therein; that she received slips of paper from the physician, and copied them into the record, and that was all she knew about them. The record was offered as evidence to show that the statements therein made were true. As handed to the witness by the physician, they were simply statements of the physician as to what the patient had said to him, or as to the diagnosis made by the physician. The records were comparatively recent. It was not shown that the physician was not living and within the jurisdiction of the court. No necessity was shown therefore for the introduction of this hearsay testimony. For aught that appeared there was better evidence. Under these circumstances the records were not admissible in evidence. The reason on which the general rule was based, namely, that the record should be a record of facts of which the writer had personal knowledge, should be applied. The case was not within the above-mentioned exception to the general rule.

Assistant Not Liable from Operating Surgeon Leaving Sponge

The Supreme Court of Michigan says in the malpractice case of Brown vs. Bennett and Smith (122 N. W. R. 305) that it was the theory of the plaintiff that the defendants jointly undertook to perform an operation on her; that they, or one of them, left in the abdominal cavity one of the gauze pads or laparotomy sponges used in performing the operation; that it remained there for ten months; that this was negligence, and that for the effects of such negligence both of the defendants were liable. The trial resulted in a judgment against both of the defendants for $625.

But the Supreme Court finds no testimony tending to prove a joint undertaking of the defendants. The case for the plaintiff, it states, stated most favorable to her, was that she was advised by her physician, Bennett, who had treated her for certain disorders, that the remedy for her ailment was a surgical operation. The family of the plaintiff, including her husband, knew of this advice, consented that an operation should be performed, and that the defendant Bennett should select and arrange with some surgeon to perform the operation. They were told that Dr. Smith had been selected; that a trained nurse would be selected by him; that it was proposed that there should be present Dr. Smith, who was to receive $75, and Drs. Bennett, Crosby and Ransom, who were to be paid $10 each. The husband or father of the plaintiff, or both, agreed to procure, and did procure, $100 and gave it to Dr. Bennett, and took his receipt therefor. Afterwards they paid him $5. This money Dr. Bennett distributed as above indicated, receiving himself $10. The husband of the plaintiff, or some one for him, also paid the nurse. Every one understood that Dr. Smith would perform the operation, assisted by the other physicians.

There was some testimony to the effect that the contract made, not by the plaintiff, but by her husband and her father, was made with the defendant Bennett, and that he was to see that the operation was properly performed, and would guarantee a cure. But this *did not tend to prove a joint* undertaking by these defendants to perform the operation. It was said in the brief for the plaintiff that "the husband of the plaintiff agreed to employ Dr. Bennett and Dr. Smith to perform this operation," but it was the not uncommon case of a practicing physician advising a patient to submit to a surgical operation to be performed, not by himself, but by some surgeon of reputation, skill and experience, for which operation, with the consent of his patient, he makes the necessary arrangements, in performing which he assists the operating surgeon as directed or advised. The operation was not performed by these defendants jointly. Dr. Smith performed it, as his testimony and that of each of the physicians and of the nurse conclusively showed.

In accordance with modern methods, the operation was an organized performance. Dr. Crosby administered the anesthetic. That was his duty and responsibility. Drs. Bennett and Ransom assisted the operating surgeon. "They stood with me," Dr. Smith testified, "at the side of the patient and assisted me as I directed; that is, they retracted the sides of the wound when it was open, pulled them apart, the sides of the wound. They helped in regard to sponging up blood, and perhaps occasionally caught a spurting vessel when it was cut, and that is about all, generally. I performed the operation. The duty of Dr. Ransom was practically the same as Dr. Bennett." The nurse had charge of the sponges before and after they were used, and counted them before and after the operation. That was her duty. The operating surgeon, having inserted the large sponge or pads, and having removed all of them in the immediate field of operation, relied on the nurse and her assurances that all sponges were accounted for, and closed the wound.

Undoubtedly each case of this nature must stand on its own facts. The length of time required to perform the operation, the nature of the operation itself, as whether the field is deep in the abdomen, the number of pads or sponges used to keep the field of operation clear, the opportunity or chance for one or more of the pads to be displaced, rolled on itself, and hidden, all of these and other considerations measure the required skill and care of the surgeon.

It must be considered as established in this case that a sponge or pad was left in the abdomen, and that an injury to the plaintiff was the consequence. It was not claimed, and was not to be supposed, that any one was intentionally at fault. Both of the defendants were men whose general professional knowledge and skill were unquestioned and undoubted. They were not engaged in a trespass. Neither was employed by the other. Each was required to exercise ordinary skill and care. But direction and control of the operation were both with one man. Whether responsibility for what occurred is rested on contract or on negligent performance of duty, there is no rule of law which under the undisputed facts impute want of skill or care by Dr. Smith to Dr. Bennett. The jury should have been so instructed.

As to Dr. Smith, it is held that the court did not acquire jurisdiction over him, because he was a non-resident of the county where sued and under the circumstances could not be held to come within the Michigan statute, which, in effect, provides that what is termed an action of trespass on the case against two or more defendants may be brought in any county where one or more of them resides or is found.

The conclusions are held to require a reversal of the judgment, and no new trial.

1 *Treatment of Pulmonary Tuberculosis Based on the Assumption that the Dietetic Cause of the Disease is Lime Starvation. J. F. Russell, New York.
2 Is There a Venereal Peril for Us? J. Van R. Hoff, U. S. Army.
3 *Hemolysis and its Diagnostic Significance in Cancer and Tuberculosis. F. Smithies, Ann Arbor.
4 Atropin as a Hemostatic. W. F. Waugh, Chicago.
5 *A Statistical Study of Alcoholism as a Causative Factor in Insanity. C. R. McKinniss, Norristown, Pa.

1. Treatment of Pulmonary Tuberculosis.—The special aim of Russell's treatment is to supply lime phosphate, casein, and hydrochloric acid together. Neither alone will answer. They must all be present in the stomach at the same time. The addition of dilute hydrochloric acid to milk and eggs accomplishes this endeavor. With the exception that vegetable juice is no longer prescribed and that the total amount of food consumed is less, the use of this acid is the only notable change made in the treatment heretofore employed. Vegetable juice, glycerin and calcium chlorid have been discontinued. It is now probable that the good effects of vegetable juice were chiefly due to its acidity; of glycerin to its power of extracting enzymes. Calcium chlorid is formed in milk when hydrochloric acid is added. Russell believes that the results so far obtained give sufficient promise of an improvement in the treatment of the tuberculous in the home climate to warrant their publication. The experiment is not yet completed. There are 25 of the original number of patients still under treatment. Further reports will be made until the work is finished.

3. **Hemolysis in Cancer and Tuberculosis.**—The results furnishing the basis of Smithies' communication are based on the findings in 85 patients affected with various ailments. Some were very interesting, particularly the cancer patients, the syphilitics, the tuberculous patients, and those affected with non-malignant diseases, but with diseases frequently productive of anemia, as Graves' disease, pernicious and severe secondary anemia, Addison's disease, etc. Of the malignant tumors, in the main, serum from moderately advanced and advanced cases reacted well, while recent tumors either caused poorly manifested reaction or none at all. The cases which did not react at all were one early carcinoma of the prostate, one scirrhus carcinoma of the stomach, and one early malignant tumor of the breast. There were two "undetermined" reactions, namely a late cancer of the breast and an early cancer of the uterus. There was one case of "reverse hemolysis," first emphasized by Crile. Both these patients had moderately advanced lesions. Six patients with tuberculosis showed negative reaction, and a like number are for fairness recorded as "undetermined." Of 12 cases of syphilis, 8, or 65 per cent., were negative, while 3 were classed as "undetermined." In all, the reactions were slightly manifested. One case—a patient with tertiary lesions and grave anemia—exhibited positive reaction. Of 25 patients affected with various more or less serious diseases, selected at random, 5, or 20 per cent., exhibited positive reaction. Of 25 patients ill, but clinically non-cancerous, 6 were classed as "undetermined." These were respectively severe acne, chronic parenchymatous nephritis, old rheumatic endocarditis, gall-stones with jaundice, neurasthenia, and pernicious anemia. One case of chorea—a young female with anemia—exhibited "reverse hemolysis." Of the clinically normal individuals—19 in number—one gave slight positive reaction, while 92.7 per cent. were negative. It seems that the blood serum of the majority of patients affected with malignant disease is capable of destroying normal red blood cells. It also appears that while this fact is very interesting from a clinical and etiologic standpoint, similar manifestations are possible, in non-cancerous patients. It should be emphasized that while the seroreactions for cancer and tuberculosis may furnish valuable and interesting information, they cannot be accepted as sole or deciding evidence. In confirmation of clinical findings they may be of importance, but as with other laboratory tests, of like nature, they cannot take the place of careful anamneses, careful examination of the patients from every viewpoint, and the adoption of clinical measures which have been proved feasible and dependable.

5. **Alcohol as a Causative Factor in Insanity.**—McKinniss' study includes 520 male patients. In 46 per cent. of these, alcohol either alone or in combination, was an important etiologic factor. In 13.5 per cent. they were classed as alcoholic psychoses. In 41 per cent. of the imbeciles and 34.5 per cent. of the epileptics, alcohol was responsible for their commitment.

6. **Relation of Tuberculosis to Infant Mortality.**—Von Pirquet says that if we go carefully into a detailed study of the possibilities of infection, we find in nearly every case of tuberculous infants another person in the neighborhood who has an open tuberculosis. Whether the infection is directly through droplets containing tuberculous germs which are coughed out by the infected person and then breathed in by the child, or by bacilli taken in from the dust of the room in which tuberculous sputum has been dried out, is a question which has not yet been decided. In comparison with the danger of infection from other human beings in the neighborhood, that of infection through tuberculous milk is probably rather small. Still, the milk of cows with tuberculous udders very often contains tubercle bacilli, and we must consider it dangerous, and therefore remove all tuberculous cows from farms that supply milk for babies; if this is not done, or if we do not know the condition of the milk, then it must be boiled. *The most important way to prevent tuberculosis in infants is, however,* to be careful that the baby does not come in contact with anyone who is likely to have tuberculosis of the lungs.

8. **Posture in Obstetrics.**—King maintains that the recumbent posture during labor is much overdone, and that it often does harm by prolonging labor, by exhausting the woman, and sometimes leading to the persistence of faulty presentations. By persistently maintaining the recumbent posture, the woman is deprived of one of the chief factors of power—the factor of thigh pressure on the walls of the abdomen and uterus, which comes into play when she assumes a sitting, kneeling or squatting posture. This thigh posture is also the natural means by which transverse presentations are either altogether prevented, or, when they occur, are corrected. The act of squatting as usually practiced is not a symmetrical proceeding. Usually, in squatting, one foot is placed flat on the ground and in advance of the other, while this other foot, considerably posterior to the first, rests its toes only on the ground. The thigh of the forward foot will assume a more or less acute angle with the woman's spinal column and will come in contact with the abdomen over a large surface extending from the groin to a line considerably above the umbilicus; while the thigh of the posterior foot will be almost horizontal, and will have a much more limited surface of contact on the lower lateral part of the abdomen only. The direction of pressure by the thigh of the forward foot will be obliquely upward and toward the median line; the direction of pressure by the thigh of the posterior foot will be almost horizontal from without inward with a little upward lift.

In shoulder and arm presentations, if the woman in squatting always places that foot forward which agrees with the side of the abdomen toward which the child's breech is directed, the pressure of this thigh will come into forcible contact with the back of the child, and lift it and the breech end up toward the median line and ensiform cartilage; while the other thigh (corresponding to the foot that is placed posteriorly and resting on its toes) will press on the abdomen low down, over a smaller surface, and coming in contact with the projecting head of the child will lever it off of the iliac fossa, inward toward the median line, and thus into the pelvic brim, and so a head presentation is produced. And if, instead of squatting, the method of unsymmetrical kneeling is adopted, in which the woman kneels on one knee, the same rule is to be followed, the foot flat on the ground must be the one corresponding to that side of the abdomen toward which the breech is directed. Whichever method be tried, it is important that the woman maintain the selected posture long enough to have a few labor pains.

10. **Biology as Basis of Infant Feeding.**—Neither biochemistry, nor the question of the best producing power of food, nor the quantitative manipulation of the ingredients of various milks, Chapin says, can form alone a broad enough basis for scientific infant feeding. They may all be employed but must be subordinated to their proper place by biology. This science, however, will always put the emphasis on growth as the largest factor in early life. It likewise for the first time in the history of this question considers the developmental as well as the nutritive functions of milk in connection with the evolution of the particular digestive tract it is intended to serve. Along this same line it will incidentally show how far

various milks are interchangeable and suggest methods of making them so.

14. **Postepileptic Albuminuria.**—In studying a disease whose etiology is so complicated as that of epilepsy, Munson shows that a symptom such as the passage of albumin into the urine after seizures should not be overlooked. The possibilities that this albuminuria is due to an old nephritis which has passed unrecognized—and the nephritis might also have etiologic relationship to the epilepsy—makes it of importance in the study of the causation of the disease. Munson examined 34 patients at the Craig colony. Post-epileptic albuminuria occurred in 28.4 per cent. of the males, and in 12.3 per cent. of the females, or in 21.5 per cent. of the whole number of cases. As regards the kind of seizure in both males and females the entire number of seizures was made up of about 75 per cent. severe and of 25 per cent. mild attacks. Of the seizures followed by albuminuria 81.5 per cent. were severe and 18.4 per cent. mild, these figures being about those for each of the two sexes as well as for their average. It is thus seen that the occurrence of postepileptic albuminuria is greater in males and after severe seizures than it is in females and after mild attacks.

One of the most striking facts brought out in this work is that albumin is always accompanied by casts. The sediment picture is of all degrees—in some urines but one or two casts were to be found in a drop of sediment, while in others the field would be crowded with them. Microscopic fields containing 5 or 10 casts were not uncommon. Practically all varieties of cast were found, though, as may be expected, cellular varieties were rare. So severe is the picture presented in some of these cases that had the urine been received at the laboratory without clinical data, the guess would have been natural that the urine was from a case of severe nephritis. After the seizure, the casts persist much longer than the albumin.

It seems probable from the evidence submitted that there is renal congestion following many severe and some mild seizures. This alone is sufficient to account for the albuminuria, and perhaps for some of the casts. There are not a few cases in which signs of chronic nephritis are present on histologic examination. It seems to Munson that we have to deal with a condition which has its origin in the congestion following or associated at any rate, with the seizure and it does not seem an unfair presumption to assume that some of the chronic changes are due to the congestion, so often repeated.

33. **Extract of Corpus Luteum.**—Morley used an extract made from the corpora lutea of beef ovaries rather than an extract of the entire ovary as the consensus of opinion seems to be that the internal secretion of the ovary is produced by the yellow body. The extract is given in 5 grain doses, 3 times a day, from one-half to one hour before meals. His results in 18 cases may be summed up as follows: Five patients were cured, 12 were improved, and 1 obtained no relief. Included in the 12 patients who were improved are grouped those who are still taking the extract. A permanent cure may result in a few of those under treatment. Of the 18 patients, 14 suffered from disturbances of operation or artificial, and 4 from those of natural or physiologic menopause. While the results obtained in so small a group of cases do not warrant the drawing of any definite conclusions, still the author thinks that the results are favorable enough to justify a continuance of the treatment in other cases, where there is a disturbance incident to artificial or physiologic menopause.

41. **Chronic Infectious Endocarditis.**—In the series of 14 cases presented in this report the disease manifested itself clinically over varying periods of time. In one patient, the symptoms began two years before the real condition was recognized. One case began fourteen months before a definite diagnosis was made. Another patient probably suffered from the disease for more than two years, and in the earlier part of the illness the diagnosis of typhoid was made for a condition which was, in all probability, infectious endocarditis, the diagnosis having been based on the fact that there was fever and splenic enlargement. No rose spots were found; there was no diarrhea, and the Widal reaction was negative throughout.

hydrochloric acid is added. Russell believes that the results so far obtained give sufficient promise of an improvement in the treatment of the tuberculous in the home climate to warrant their publication. The experiment is not yet completed. There are 25 of the original number of patients still under treatment. Further reports will be made until the work is finished.

3. **Hemolysis in Cancer and Tuberculosis.**—The results furnishing the basis of Smithies' communication are based on the findings in 85 patients affected with various ailments. Some were very interesting, particularly the cancer patients, the syphilitics, the tuberculous patients, and those affected with non-malignant diseases, but with diseases frequently productive of anemia, as Graves' disease, pernicious and severe secondary anemia, Addison's disease, etc. Of the malignant tumors, in the main, serum from moderately advanced and advanced cases reacted well, while recent tumors either caused poorly manifested reaction or none at all. The cases which did not react at all were one early carcinoma of the prostate, one scirrhus carcinoma of the stomach, and one early malignant tumor of the breast. There were two "undetermined" reactions, namely a late cancer of the breast and an early cancer of the uterus. There was one case of "reverse hemolysis," first emphasized by Crile. Both these patients had moderately advanced lesions. Six patients with tuberculosis showed negative reaction, and a like number are for fairness recorded as "undetermined." Of 12 cases of syphilis, 8, or 65 per cent., were negative, while 3 were classed as "undetermined." In all, the reactions were slightly manifested. One case—a patient with tertiary lesions and grave anemia—exhibited positive reaction. Of 25 patients affected with various more or less serious diseases, selected at random, 5, or 20 per cent., exhibited positive reaction. Of 25 patients ill, but clinically non-cancerous, 6 were classed as "undetermined." These were respectively severe acne, chronic parenchymatous nephritis, old rheumatic endocarditis, gall-stones with jaundice, neurasthenia, and pernicious anemia. One case of chorea—a young female with anemia—exhibited "reverse hemolysis." Of the clinically normal individuals—19 in number—one gave slight positive reaction, while 92.7 per cent. were negative. It seems that the blood serum of the majority of patients affected with malignant disease is capable of destroying normal red blood cells. It also appears that while this fact is very interesting from a clinical and etiologic standpoint, similar manifestations are possible, in non-cancerous patients. It should be emphasized that while the seroreactions for cancer and tuberculosis may furnish valuable and interesting information, they cannot be accepted as sole or deciding evidence. In confirmation of clinical findings they may be of importance, but as with other laboratory tests, of like nature, they cannot take the place of careful anamneses, careful examination of the patients from every viewpoint, and the adoption of clinical measures which have been proved feasible and dependable.

5. **Alcohol as a Causative Factor in Insanity.**—McKinniss' study includes 520 male patients. In 46 per cent. of these, alcohol either alone or in combination, was an important etiologic factor. In 13.5 per cent. they were classed as alcoholic psychoses. In 41 per cent. of the imbeciles and 34.5 per cent. of the epileptics, alcohol was responsible for their commitment.

6. **Relation of Tuberculosis to Infant Mortality.**—Von Pirquet says that if we go carefully into a detailed study of the possibilities of infection, we find in nearly every case of tuberculous infants another person in the neighborhood who has an open tuberculosis. Whether the infection is directly through droplets containing tuberculous germs which are coughed out by the infected person and then breathed in by the child, or by bacilli taken in from the dust of the room in which tuberculous sputum has been dried out, is a question which has not yet been decided. In comparison with the danger of infection from other human beings in the neighborhood, that of infection through tuberculous milk is probably rather small. Still, the milk of cows with tuberculous udders very often contains tubercle bacilli, and we must consider it dangerous, and therefore remove all tuberculous cows from farms that supply milk for babies; if this is not done, or if we do not know the condition of the milk, then it must be boiled. The most important way to prevent tuberculosis in infants is, however, to be careful that the baby does not come in contact with anyone who is likely to have tuberculosis of the lungs.

8. **Posture in Obstetrics.**—King maintains that the recumbent posture during labor is much overdone, and that it often does harm by prolonging labor, by exhausting the woman, and sometimes leading to the persistence of faulty presentations. By persistently maintaining the recumbent posture, the woman is deprived of one of the chief factors of power—the factor of thigh pressure on the walls of the abdomen and uterus, which comes into play when she assumes a sitting, kneeling or squatting posture. This thigh posture is also the natural means by which transverse presentations are either altogether prevented, or, when they occur, are corrected. The act of squatting as usually practiced is not a symmetrical proceeding. Usually, in squatting, one foot is placed flat on the ground and in advance of the other, while this other foot, considerably posterior to the first, rests its toes only on the ground. The thigh of the forward foot will assume a more or less acute angle with the woman's spinal column and will come in contact with the abdomen over a large surface extending from the groin to a line considerably above the umbilicus; while the thigh of the posterior foot will be almost horizontal, and will have a much more limited surface of contact on the lower lateral part of the abdomen only. The direction of pressure by the thigh of the forward foot will be obliquely upward and toward the median line; the direction of pressure by the thigh of the posterior foot will be almost horizontal from without inward with a little upward lift.

In shoulder and arm presentations, if the woman in squatting always places that foot forward which agrees with the side of the abdomen toward which the child's breech is directed, the pressure of this thigh will come into forcible contact with the back of the child, and lift it and the breech end up toward the median line and ensiform cartilage; while the other thigh (corresponding to the foot that is placed posteriorly and resting on its toes) will press on the abdomen low down, over a smaller surface, and coming in contact with the projecting head of the child will lever it off of the iliac fossa, inward toward the median line, and thus into the pelvic brim, and so a head presentation is produced. And if, instead of squatting, the method of unsymmetrical kneeling is adopted, in which the woman kneels on one knee, the same rule is to be followed, the foot flat on the ground must be the one corresponding to that side of the abdomen toward which the breech is directed. Whichever method be tried, it is important that the woman maintain the selected posture long enough to have a few labor pains.

10. **Biology as Basis of Infant Feeding.**—Neither biochemistry, nor the question of the best producing power of food, nor the quantitative manipulation of the ingredients of various milks, Chapin says, can form alone a broad enough basis for scientific infant feeding. They may all be employed but must be subordinated to their proper place by biology. This science, however, will always put the emphasis on growth as the largest factor in early life. It likewise for the first time in the history of this question considers the developmental as well as the nutritive functions of milk in connection with the evolution of the particular digestive tract it is intended to serve. Along this same line it will incidentally show how far

various milks are interchangeable and suggest methods of making them so.

14. **Postepileptic Albuminuria.**—In studying a disease whose etiology is so complicated as that of epilepsy, Munson shows that a symptom such as the passage of albumin into the urine after seizures should not be overlooked. The possibilities that this albuminuria is due to an old nephritis which has passed unrecognized—and the nephritis might also have etiologic relationship to the epilepsy—makes it of importance in the study of the causation of the disease. Munson examined 34 patients at the Craig colony. Post-epileptic albuminuria occurred in 28.4 per cent. of the males, and in 12.3 per cent. of the females, or in 21.5 per cent. of the whole number of cases. As regards the kind of seizure in both males and females the entire number of seizures was made up of about 75 per cent. severe and of 25 per cent. mild attacks. Of the seizures followed by albuminuria 81.5 per cent. were severe and 18.4 per cent. mild, these figures being about those for each of the two sexes as well as for their average. It is thus seen that the occurrence of postepileptic albuminuria is greater in males and after severe seizures than it is in females and after mild attacks.

One of the most striking facts brought out in this work is that albumin is always accompanied by casts. The sediment picture is of all degrees—in some urines but one or two casts were to be found in a drop of sediment, while in others the field would be crowded with them. Microscopic fields containing 5 or 10 casts were not uncommon. Practically all varieties of cast were found, though, as may be expected, cellular varieties were rare. So severe is the picture presented in some of these cases that had the urine been received at the laboratory without clinical data, the guess would have been natural that the urine was from a case of severe nephritis. After the seizure, the casts persist much longer than the albumin.

It seems probable from the evidence submitted that there is renal congestion following many severe and some mild seizures. This alone is sufficient to account for the albuminuria, and perhaps for some of the casts. There are not a few cases in which signs of chronic nephritis are present on histologic examination. It seems to Munson that we have to deal with a condition which has its origin in the congestion following or associated at any rate, with the seizure and it does not seem an unfair presumption to assume that some of the chronic changes are due to the congestion, so often repeated.

41. **Chronic Infectious Endocarditis.**—In the series of 14 cases presented in this report the disease manifested itself clinically over varying periods of time. In one patient, the symptoms began two years before the real condition was recognized. One case began fourteen months before a definite diagnosis was made. Another patient probably suffered from the disease for more than two years, and in the earlier part of the illness the diagnosis of typhoid was made for a condition which was, in all probability, infectious endocarditis, the diagnosis having been based on the fact that there was fever and splenic enlargement. No rose spots were found; there was no diarrhea, and the Widal reaction was negative throughout.

The infectious organisms found in Billings' 14 cases were as follows: The pneumococcus, 11 cases; streptococcus, 3 cases. The organisms obtained in the 11 patients suffering from pneumococcemia had many of the morphologic characteristics of streptococci. Study of the organisms in culture and in animals proved that they were the pneumococcus. In one patient of this series the infectious endocarditis followed pneumonia. Tonsillitis had occurred in two cases. In the other patients the source of infection could not be learned. There can be no doubt whatever that simple local infection like tonsillitis, as well as abscess of the aural cavities, infection of the postnasal space of the antra, and so forth, may be the port of entry.

In some cases of this series the infection was implanted on an old endocardial or valvular scar. An old heart lesion existed in 7 patients, of whom 6 had suffered from rheumatic fever and one from chorea. Two of the patients gave no history, and the question of previous heart lesion was in doubt. In 5 the infection had apparently been implanted on a normal endocardium or valve. The valves involved in the 14 cases were as follows: aortic valve alone, 1; mitral alone, 7; pulmonary semilunar alone, 1; aortic and mitral together, 5; mitral and tricuspid together, 1. The evidence of heart lesion, as manifested by murmur, may be absent in the primary cases during the earlier part of the disease, and sometimes throughout it. The prognosis with the present knowledge or want of knowledge in reference to any specific treatment is, in his experience, bad.

The treatment should be absolute rest, with good air, sunshine, as much simple liquid and soft solid nourishment as may be given, and the use of those remedies which will conserve the patient's strength and the functions of the organs without too much mischievous interference. Inoculations of patients with large doses of their own dead pneumococci was always harmful. Observation of patients injected with even small doses (2,500,000) leads Billings to believe that this form of treatment for infectious endocarditis due to the pneumococcus is not only devoid of benefit to the patient, but probably is harmful.

42. **Venous Pulse in Paroxysmal Tachycardia.**—From the point of view of the venous pulse all cases of paroxysmal tachycardia apparently fall into a group which includes those cases in which the venous pulse assumes the "ventricular" or "positive" type, and there is no evidence of any contraction of the auricles. It is important to distinguish between cases of idiopathic paroxysmal tachycardia, with sudden onset and cessation, and cases of simple rapid heart action beginning and ending more or less gradually.

43. **Relation of Iodin to Structure of Human Thyroids.**—Marine and Lenhart conclude that active thyroid hyperplasia is present in all developing goiters in all animals. All thyroid hyperplasia so far as they can determine, is anatomically, chemically (iodin) and biologically the same. Thyroid hyperplasia develops in both normal and colloid glands. Colloid glands, anatomically, chemically and biologically, are the nearest approach to the normal gland that hyperplasias can become, and obey all the known biologic laws of normal glands in so far as these laws are at present known. The various degenerations, hemorrhages and cysts are secondary and complicating changes engrafted on to the three fundamental types of normal hyperplastic and colloid glands. Iodin is necessary for normal thyroid activity. The iodin content varies inversely with the degree of hyperplasia. The percentage of iodin present in the thyroids is variable, but there is a quite constant minimum percentage necessary for the maintenance of normal or colloid gland structure. Iodin is taken up rapidly by the thyroid, the rapidity depending on the degree of active hyperplasia. Mild degrees of thyroid hyperplasia accompany or follow many of the chronic nutritional disturbances without detectable clinical symptoms referable to the thyroid. Exophthalmic goiter is constantly accompanied during the progressive stage of the disease by thyroid hyperplasia and the iodin percentage varies inversely with the degree of hyperplasia. In endemic cretinism the fibrous overgrowth with atrophy of the gland cells is consequent on active hyperplasia and is associated with very low iodin content. In myxedema the anatomic and iodin changes are similar to those of cretinism.

44. **Active and Inactive Serum in Test for Syphilis.**—Although the use of active serum gives more delicate results in syphilis, Swift says it is not to be recommended, because it gives too high a percentage of reactions with non-syphilitic serums. When inactive serum is employed in the proportion of twice the amount of guinea-pig serum, a high percentage of positive reactions is obtained in syphilis, and non-syphilitic serums, giving a positive reaction with active serum, give a negative reaction when the same serum is inactivated. The use of inactive serum instead of active serum renders the Noguchi method more accurate and nearly as convenient as originally described, and still easier of application than the Wassermann method. The amount of blood required can readily be obtained without resorting to venous puncture, so that it is possible to make frequent tests without too much inconvenience to the patient.

45. **Lesions Resulting From Bile Salts.**—Sellards found that the injection of guinea-pigs with the lethal dose of sodium glycocholate produces lesions in the stomach which are relatively specific. These lesions are closely analogous to those produced by the direct injection of bile into the pancreatic duct. Injection of sodium taurocholate into the parotid gland of dogs produces lesions which are less extensive than for corresponding conditions in the pancreas. An extract of the pancreas is actively hemolytic *in vitro*. Its behavior toward blood serum and corpuscles in test-tube experiments is exactly analogous to that of the bile salts. The pancreatic ferments might, theoretically, augment the lesions produced, *in vivo*, by bile. The hemorrhage in the acute pancreatitis caused by bile would, judging from the hemolytic reactions, tend to neutralize both the toxic action of the bile salt and also of the pancreatic secretions.

46. **Effect of Hexamethylenamin on Guinea-Pigs.**—Frothingham found that hexamethylenamin, when given subcutaneously in guinea-pigs, either in single doses or in repeated doses, produces necrosis of the muscle and cellular reaction at the point of inoculation. It also causes congestion of the stomach vessels, and in some cases hemorrhage into the mucosa, with ulcer formation. Frothingham says that this work offers no proof as to what lesions in man may be the cause of symptoms occasionally produced by hexamethylenamin, but it suggests that these lesions are not organic. The most interesting points brought out are the enormous amount of hexamethylenamin a guinea-pig can receive subcutaneously without apparent injury, and the fact that hexamethylenamin is another drug to add to the list of those that may cause hemorrhage in the stomach walls of guinea-pigs.

53 *Tuberculosis and its Treatment by Mercury. B. L. Wright, U. S. Navy.
54 Correlation of Pathologic States Between the Thyroid and Prostate Glands and the Uterus, Chiefly Bearing on Epilepsy and Other Nervous Disorders. E. Dupuy, Paris.

53. **Tuberculosis.**—Since the latter part of October, 1908, Wright has made it a routine practice to examine the feces as well as the sputum of every tuberculous patient, and in almost every instance he has demonstrated the presence of the tubercle bacillus in the feces, in many cases in which repeated examinations of the sputum were negative and in which the pathologic lesions of the disease were apparently confined to the lungs. He has also found the bacillus in the feces in cases in which it had long since disappeared from the sputum and the patients appeared to be otherwise clinically

cured. With the above facts in view, it must be admitted, he says, that tuberculosis is primarily a general systemic infection, a bacteremia, but never a local condition under any circumstances. Since February, 1908, Wright has advocated the treatment of this disease by the deep muscular injections of mercury. Experience has led him to modify in some degree the dosage he first used and recommended. He says: Begin with grain 1/15 of mercury succinimid; give injections every other day; slowly increase the dose until a slight tenderness of the gums or a slight diarrhea is produced, then reduce the dose until these symptoms are overcome, and continue the injections until thirty have been given. Then give the patient a rest for two weeks; at the end of this interval of rest resume injections, using the dose used at the last previous injection, and continue on this dose as long as the patient continues to improve, up to thirty injections; if any untoward symptoms arise, or the patient does not appear to be doing well, reduce the dose, or alternate injections of mercury with injections of arsenious trioxid, gr. 1/30 and ferrous citrate, gr. 1/2, for a short time. Each series of injections should consist of thirty, with two weeks of rest intervening. As treatment progresses smaller doses of mercury are required. At the end of one year's treatment a rest of from 2 to 3 months should be given, when, if the patient is not cured, treatment should be resumed. As many patients with syphilis do not respond entirely to mercury but do better when this drug is combined with arsenic, so many patients with tuberculosis do better when arsenic is added to the doses of mercury.

Good results from this method of treatment have been obtained irrespective of what organ or tissue has shown local involvement. Of 83 patients treated by this method during 1908, 89 per cent. were improved, 7 of whom were cured. Of 24 cases of secondary ulcerative tuberculosis of the larynx, 20 were cured; the 4 remaining patients died within two months after admission, post-mortem showing in each case advanced lesions of practically all the organs, and yet in one of these the extremely marked ulcerative process in the larynx was completely healed. Four patients with general glandular involvement, 3 of whom had a suppurative process of the anterior cervical glands, were cured. One patient with tuberculous epididymitis was cured.

68. **Chronic Appendicitis.**—In the routine examination of digestive patients by colon dilatation, Bastedo noted some three years ago, that acute pain or tenderness in the region of McBurney's point or dilatation of the colon regularly meant appendicitis. He has many cases in which the finding has been proved correct by operation, and in every patient operated on in whom the sign was positive, a diseased appendix has been found. He has a few cases thought to be appendicitis in which the sign was negative; in some of these from one to three years have passed without any appendix manifestations; in the others operation was performed and the appendix found normal. In no case with the sign negative was appendicitis found at operation. Bastedo asks all surgeons to employ this method so that its exact value may be determined, for it would seem to be especially useful in cases in which slight tenderness to finger point pressure at McBurney's point still leaves doubt as to the advisability of operation. Pain and tenderness are regularly brought out at the site of old abdominal operations, and occasionally in various parts of an abdomen that has not been operated on. Their occurrence in the same spot at repeated examinations suggests adhesions.

69. **Psychoses During Pregnancy and Puerperium.**—One thousand women have been systematically and individually studied by Ballintine in reference to the causes, symptoms and outcome of their insanity, and the findings carefully recorded. It was found that 457 of these women had borne children (including 5 illegitimate pregnancies). In 141, or 30 per cent. of these cases, the onset of the psychosis occurred during either gestation, the puerperium, or lactation. Agreeing with the results of similar studies recently made by others, Ballintine found that the study of the 141 cases taught that puerperal insanity, so-called, presents no characteristic or constant symptomatology or pathology. On the contrary there are several forms of insanity that may occur during the puerperium or during pregnancy and these are forms that occur as frequently in the non-puerperal as in the puerperal state.

Considered etiologically, the puerperium in many cases was only an exciting or determining cause of the mental breakdown in the predisposed. In other cases the real causes of the psychosis were due to some accident at childbirth, or some other intercurrent disease or infection. In still other cases childbirth was simply incidental to the psychosis.

The majority of cases of insanity occurring in women before the climacteric may be included in three large groups, namely—dementia præcox or the deteriorating psychoses; manic-depressive psychoses; and infective-exhaustive psychoses. Eighty-seven per cent. of the 141 women under consideration glided readily into these three well-known groups of acute insanities. Dementia præcox, the largest group, included 46 persons, four being admitted more than once, bringing the total admission up to 50. The manic-depressive psychoses included 33 persons, 35 admissions. The infectious exhaustive psychoses and allied forms included 38 admissions. Other forms included 20 admissions. Among the patients under consideration were a few in whom a careful study shows that some premonitory symptoms presented themselves before gestation, but the condition was not recognized and in nearly all of these women the puerperal condition of childbirth was believed to be the cause of the insanity, and so recorded in the medical certificate on which they were admitted to the hospital.

77. **Internal Splint in Fractures.**—Pearse uses a steel splint or splice fastened with screws directly to the replaced fragments of the bone, as first advocated and employed by Lane.

81. **Injury to the Heart.**—The first case was a penetrating stab wound of the right ventricle. The wound penetrated the left pleural cavity. The pericardium could be felt but no puncture was found. A gauze plug was tightly forced into the wound to stop any bleeding. On account of great shock, radical procedure was deferred. The patient was almost pulseless; he was dyspneic. A dressing was applied; morphin sulphate, gr. 1/4, was given hypodermically once. Physiologic saline solution was given repeatedly hypodermically and by the rectum. Three days later, signs of a pyohemothorax were appearing. The left pleural cavity was almost entirely full of fluid. One inch of the sixth rib was removed in the left posterior axillary line. The pleural cavity was full of infected blood; a rubber drainage tube was introduced. The course now was one of empyema of the thorax. The patient grew gradually weaker and died seventeen days after the beginning of his trouble. From the postmortem findings it was evident that this was a case of penetrating wound of the right ventricle which would have healed without operation. Unfortunately death, caused by sepsis, intervened.

The second case was a non-penetrating gunshot wound of the apex of the left ventricle and of the margin of the left lung. An incision three inches long, parallel to the papillary line, was made extending through the gunshot wound. One inch of the fourth and fifth ribs was resected (one-half inch of the cartilaginous and one-half inch of the bony portion of the respective ribs).

106. **Phases of Sarcomata.**—Of 11 cases reported by Barnhill only one could be called an early operation; in 4 there has been no sign of recurrence. The mortality is 63 per cent., the average life after operation being 16 months. In 3 of these cases the *x*-ray treatment was used—one patient has remained well for 5 years, another for 15 months, and the third is still under treatment. Barnhill is persuaded that without its use he should have had a recurrence in a case of sarcoma of the sacrogluteal region. He advocates the *x*-rays or the Coley toxins as supplements or auxiliaries of surgical measures. Of all patients operated on early, in the general line of cases as they come to the surgeon, probably not more than 25 per cent. remain permanently cured. These results could be greatly improved if cases were reported earlier and surgeons were prompt in operating in all suspected cases. Coley's statistics, including about 500 cases of inoperable sarcoma treated by the mixed toxins, show that 10 per cent. recover. This 10 per cent. is, of course, of the inoperable cases—uncured and uncurable, in all probability by any other means. Thus we have, with the combination of operative measures and the Coley serum, a chance to save about 35 per cent. Now, if, in addition to this, the *x*-ray treatment be employed, to prevent recurrence and complete the cures after excision, it is not improbable that we would be able to save another 10 or 15 per cent. of those affected with this type of malignant growth.

116. **Bacterial Inoculations in Typhoid.**—Eight patients were injected by Nichols after the method of Smallman, with from 1 to 4 large doses (150 to 600 millions) each, at intervals of several days, according to the course of the case. One case was complicated with wild delirium, one with intestinal hemorrhage and relapse, one with a relapse, two were prolonged to 31 and 33 days; aside from these, the cases were mild to moderate, and uncomplicated. There was no uniform effect of the injections on the temperature, and in most instances the temperature course seemed unaffected. Only one injection (300 millions) was followed by any notable local reaction or marked soreness at the site of inoculation. The reactions seemed less than would be expected after similar injections in healthy subjects. No bad results from the inoculations were apparent. No effect on the clinical conditions, in the way of either improvement or aggravation of the symptoms was definitely demonstrable. The patients *did very well,* but that may have been coincidental.

Three patients were treated by a different system—smaller doses at regular and frequent intervals—that is, 50 millions every other day. One was a mild case of 24 days, with a slight relapse. The other two were very ill on admission, and had prolonged febrile courses of 45 and 40 days; but the improvement in one of these cases was so satisfactory that if the injections could be credited with the result the usefulness of the treatment would be confirmed.

The results in the whole series are quite inconclusive. They probably show that typhoid vaccine, even in quite large doses, produces no harmful effects; but to what extent the favorable course in most of the cases was effected by the inoculations is indeterminate. Relapses certainly were not prevented.

2. **Improved Method of Removing the Testicle.**—In a case of malignant disease of the testicle, Bland-Sutton determined to remove the testicle, the spermatic cord, with its arteries, veins, and lymphatics, and the associated lymph glands which lie on the inferior vena cava. The scrotum was freely incised and the right testicle was exposed and freed from its investments, and the spermatic cord was isolated as far as the internal abdominal ring. After much of the loose scrotal skin had been removed, the bleeding vessels were ligated with fine silk, and the testicle was enveloped in a fold of sterilized gauze. The second stage consisted in making a free incision of the right abdominal wall in the line of the linea semilunaris from the costal arch to the opening in the inguinal canal. The incision divided all the structures of the anterior abdominal wall, down to the peritoneum. Gentle tension on the testicle soon showed the position of the spermatic vessels lying in the loose areolar subperitoneal tissue. In order to isolate them, they were surrounded by a thin silk ligature just before their termination in the vena cava. The vas deferens and its artery were ligatured and divided at the brim of the pelvis.

At this stage the retroperitoneal tissues of the right lumbar region were well exposed and examined for enlarged lymph glands. Bland-Sutton found one on a level with the third lumbar vertebra, lying on the anterior face of the vena cava; although as large as a haricot bean it shelled out easily. A careful search was made for other lymph glands but without success. In spite of the large area of tissue opened up, there was little loss of blood, and the only vessels, apart from the spermatics, which required to be ligated were those divided in the scrotum and in the abdominal wall. The abdominal incision was closed by interrupted silk sutures, and the cut edges of the scrotum were brought together by sutures of thin silk. A narrow rubber tube was inserted into the depths of the wound for twenty-four hours. The wound was dressed with sterilized gauze and Gamgee tissue, held in position by a many-tail bandage, reinforced in the inguinal region by a spica bandage. Afebrile healing followed, with a rapid convalescence. The patient left the hospital on the seventeenth day after operation.

4. **Radium in Cancer.**—Butlin regards it possible by means of radium to promote the healing of epitheliomatous ulcers of very small extent, and to remove the induration around the ulcers. The cure of such conditions appears to be as satisfactory as the cure of rodent ulcers. In cases of epithelioma of any but the smallest extent we are not yet justified in advising patients whose disease is amenable to operation to try the effect of radium unless there are circumstances in the individual case which render an operation inadvisable. So far as associated affection of the lymph glands is concerned, Butlin has not yet seen anything which would warrant him in believing that the application of radium to the primary disease, even if it were successful, would avert affection of the glands, nor has he seen any case in which undoubted secondary affection of the glands was cured or decidedly benefited by the use of radium. Whether the application of radium over the glandular area before it is obviously affected will be found by-and-by to exercise a protective effect on the glands he does not know. At present the glands must be treated, as they have been hitherto, by operation.

The results which he has seen of the treatment of leucoplakia and allied conditions lead him to believe that radium only cures them by substituting thin scar-tissue for them, but does not restore the mucous membrane to the condition it was in before the development of the disease. Treatment by means of radium in such cases has, however, the great advantage over surgical removal or the use of destructive agents in that it is quite or almost painless, and that no actual inflammation and no open sore are produced by the applications when they are made by experienced operators.

6. **Abdominal Viscera and Corset.**—Lane calls attention to the disadvantage that the individual experiences from the habit of keeping the trunk constantly erect. The erect posture affects men and women differently, for the reason that the abdomen of a woman is relatively much longer than that of a man, while the female pelvis and thorax differ materially from the male. The abdominal wall of the woman is also rendered less efficient by pregnancy and by the support afforded by her dress. When the trunk is erect, there exist tendencies to the downward displacement of the viscera contained in the abdominal cavity. The several viscera are influenced by this tendency in a varying degree in proportion as they themselves vary in weight. The mechanics of the abdominal wall are such that the muscles exert a firm pressure on the viscera and tend to prevent their downward displacement. Still, in the abdomen, as well as in the body generally, the anatomy is so arranged that there must be a suitable relationship between the attitudes of activity and those of rest, or, in other words, that the erect posture, in which the viscera tend to drop, must be alternated sufficiently with a position in which all strain is taken off the viscera and the tendency for them to drop is in abeyance. This latter may be obtained by the assumption of the recumbent or of the squatting posture. In the former the viscera tend to displace upward by their own weight, while in the latter they are forced upward by the forcible apposition of the thighs.

This falling of the viscera leads to all sorts of disturbances —more or less annoying—and of more or less serious import. Lane says that the corset has not received the attention it deserves, so that by far the most important factor in the treatment of intestinal stasis and of its effects has been left in abeyance. He urges its therapeutic value on the medical profession as being the most effectual means by which the trouble to which he has called attention may be avoided or mitigated.

10. **Enumeration of Blood Corpuscles.**—Samut uses the Blenden-ocular "Ehrlich." With this instrument enumeration of corpuscles is done as follows: The drop of blood is obtained and diluted in the Thoma-Zeiss pipette and blown out onto the Thoma-Zeiss ruled slide in the usual way. When this has been placed on the microscope, five minutes are allowed to elapse. A No. 9 Leitz objective and a Blenden-ocular are used, the slit being so adjusted by means of the little knob that four squares of the central platform of the counting chamber just coincide with it. The red corpuscles are counted and the preparation may now be shifted as many times as desired, each count representing the number of corpuscles in four squares, since the slit corresponds exactly to four of the squares. The total number obtained after several such counts being divided by the number of counts gives the number of red corpuscles per field of four squares; hence division by four

gives the number per square. This number multiplied by 4,000 would represent the number of corpuscles per cubic millimeter were it not that the dilution has to be taken into account, and accordingly the result must be multiplied by 100 or 200.

Again, the Blenden-ocular may be used for the purpose of counting the leucocytes in the following manner: A dry film preparation of the blood to be examined is fixed and stained by Leishmann's or Jenner's stain. Using a No. 9 Leitz objective and a Blenden-ocular the red and white corpuscles are counted, the shutter of the ocular being at one-half or one-quarter of the total field of vision. The count is made several times through the same slit and an average of corpuscles to the field is obtained.

17 *Classification of Cases of Pulmonary Tuberculosis. W. R. Huggard.
18 Acute Lupus Erythematosus. F. Beetham and F. W. Eurich.
19 Henoch's Purpura. L. Day.

15. This subject was discussed fully in The Journal, Nov. 27, 1909, page 1831, in the Department of General News.

17. **Classification of Pulmonary Tuberculosis.**—Huggard estimates numerically the extent, the intensity and the duration of the disease from 1, the lowest grade, to 5, the highest, except that the highest grade of intensity must be taken to range from 5 to 10, so as to include excessively acute or fulminating cases. The sum of these figures will indicate the class in which the case is to be placed:

Extent: *Amount of tubercle in the lung.* E^1 = Not more than 1/20 of the volume of one lung, whether in one spot (massive), or distributed throughout both lungs (scattered). E^2 = Not more than 1/10 of the volume of one lung, whether in one spot (massive), or distributed throughout both lungs (scattered). E^3 = Not more than 1/5 of the volume of one lung, whether in one spot (massive), or distributed throughout both lungs (scattered). E^4 = Not more than 3/10 to 5/10, or roughly, ⅓ to ½ of the volume of one lung, whether in one spot (massive), or distributed throughout both lungs (scattered). E^5 = Not more than 6/10 to 10/10, or roughly ⅔ to 1, of the volume of one lung, whether in one spot (massive), or distributed throughout both lungs (scattered).

Intensity: All the conditions named under one heading need not be present at the same time. I^1 = Sluggish, with little or no rise in temperature or other general symptoms. Only slight, if any, hemoptysis. Physical signs of active disease slight, just detectable. I^2 = Slight pyrexia and night sweats; moderate loss of appetite and of strength. Physical signs of moderate activity. Bronchial catarrh, if present, slight in amount, and restricted to the area of the tubercle. I^3 = Moderate fever and night sweats; seriously impaired health; loss of strength and weight. Hemoptysis, if present, followed by continued pyrexia. Physical signs of softening or of cavity formation. Bronchitis, if present, more marked or more diffused in I^2. Recent tubercle if elsewhere than in lungs, very slight. I^4 = Grave constitutional disturbance—more pronounced than in I^3. Physical signs of greater activity. Bronchitis, if present, more marked or more diffused. Tubercle if present elsewhere, more active than in I^3. I^{5-10} = Very serious illness. Physical signs more active still. Bronchial catarrh more pronounced or more diffused. Acute or fulminating phthisis.

Duration: D^1 = not over 3 months; D^2 = not over 6 months; D^3 = not over 1 year; D^4 = not over 3 years; D^5 = over 3 years.

28 Hydatid Cyst of the Left Ventricle. Hydatid Disease in the Anglo-Egyptian Sudan. J. B. Christopherson.
29 *Burmese "Htone Na": A Peripheral Neuritis of Malarial Origin. L. G. Fink.

29. **Burmese "Htone Na."**—The object of Fink's communication is twofold: First, to establish the fact that certain forms of peripheral neuritis are of malarial origin. Second, to show in what respect these cases of malarial peripheral neuritis differ from cases of beriberi. In all cases, with one exception, seen by Fink, there was a history of repeated attacks of ague. In the majority there had been some enlargement of the spleen. In some cases the symptoms came on gradually, in others suddenly, usually after a bout of malarial fever or exposure to damp or cold.

Signs and Symptoms: Fever.—Usually there is a previous history of ague, but there may be no abnormal temperature when the neuritis supervenes. Parts affected: usually the lower extremities; sometimes upper extremities as well. The distribution is usually symmetrical.

Knee reflexes: In the early stage this has been noticed to be markedly increased, but later this is entirely lost. This happens also in beriberi. Electric reactions were not tested. Anesthesia varies in extent and degree, but is usually best marked over the front and inner aspects of the legs. Hyperesthesia of skin was not noted. The patients in the early stages usually complain of burning or shooting pains, "pins and needles," or a feeling of numbness. This may affect the lower or upper extremities, chiefly the former. Pinching the skin over the affected part usually causes no pain. Hyperesthesia of muscles is always present. Muscular wasting is very marked in severe cases. The muscles become flabby. Paresis varies as in beriberi, and may go on to complete paralysis with atrophy of muscles. Edema is usually slight, sometimes entirely absent, and, as a rule, is confined to the region of the ankles. Epigastric tenderness or uneasiness at the pit of the stomach has not been observed before or after the neuritis supervened. Furthermore, obstinate vomiting does not occur in malarial neuritis as in some cases of beriberi.

Condition of heart is normal in malarial neuritis; there is no acceleration of the pulse, no palpitations, no cardiac murmurs as in beriberi. Hence, there are no sudden deaths from malarial neuritis as in beriberi. Dyspnea does not occur in the dry variety of malarial neuritis, however severe the case may be. Alteration of voice was not noticed, whereas in beriberi the voice is said to be very hoarse. Mental disturbances are exceedingly difficult to test in native patients. The mental disturbances caused by malarial toxemia are sometimes very severe, and cases of insanity from this cause have been recorded. Optic neuritis and even complete blindness have been known to follow severe attacks of malarial fever.

From the facts noted above it will be seen that while there are many points of similarity between cases of malarial neuritis and beriberi, there are important differences, and these are attributable to the selective influence of the poisons in each case, notably to the affection of the vagus nerves in beriberi and not in malarial neuritis.

33 *Treatment of Puerperal Infection. A. Pinard.
34 Appendicitis and Diseases of the Adnexa. (L'appendicite et les maladies des annexes.) P. Segond.
35 *Kidney Operations. (Quelques reflexions à propos de 265 opérations rénales.) H. Hartmann.

33. **Puerperal Infection.**—Pinard presents in tabulated form the details of his obstetric service since 1882; the 10 tables and curves giving an instructive oversight of the results of the application of the technic he prefers. During the 26 years there were 58,213 childbirths, the total mortality in the first series of 12,580 being 0.75 per cent. and in the later series of 45,633, 0.44 per cent. His leading principle is that the parturient should be aseptic as also everything that touches her. In order to ensure this he concludes the general and local toilette with vaginal injection of an antiseptic, covering the parts with cotton thereafter. A similar vaginal injection is made at once after expulsion of the fetus and another after the third stage of labor. If there is suspicion of a chance for infection, antistreptococcus serum is injected and an intrauterine injection is given. He approves of curetting with thick fetid lochia but not otherwise, and regards it as dangerous when applied tardily. His curves show the apparent harmlessness of antistreptococcus serum while it seems to increase the resisting powers in streptococcus infection. He has gradually increased the dosage, now injecting 40 c.c. morning and night for 3 days or until all symptoms have vanished. A number of the women thus received from 300 to 600 c.c. and always, he says, to their great benefit. The morbidity has dropped from 25.76 to 5.64 per cent. since 1890, the total mortality from 0.72 to 0.18 per cent. It was only 0.03 per cent. in the 3,028 deliveries in 1907.

35. **Kidney Operations.**—Hartmann performed nephropexy in 31 cases but found that certain patients continued to suffer as before; the disturbances had evidently been of nervous origin or merely one element in multiple ptoses. Intermittent attacks of retention of urine, however, are an important indication for operative measures. In 57 cases of tuberculosis of the kidney, favorable results were attained by nephrectomy, but tuberculous epididymitis developed later in 2 out of the 15 men nephrectomized, another succumbed in less than 3 months to tuberculous meningitis and in several concomitant pulmonary lesions continued to develop. In some of the 42 women an existing pregnancy continued its course apparently unaffected by the nephrectomy. Only 4 of 11 patients with kidney stones and pyonephrosis recovered completely after a conservative operation; a fistula persisted in the others necessitating secondary nephrectomy. The mortality was 13.3 per cent. in 15 nephrectomies done for cancer; the first symptoms had been observed 3, 5 or 12 years before in a number. None of the patients has passed 4 years without recurrence; in several the recurrence developed after the third year.

39 *Pyelitis and Pyelonephritis as Complications of Measles. (Pyélites et pyélonéphrites comme complication de la rougeole.) M. de Biehler.

36. **Recurrent Vomiting in Children.**—Comby refers to recurring attacks of uncontrollable vomiting lasting for one or several days, observed generally in children between 2 and 6, who are apparently entirely well during the intervals. This singular syndrome has not attracted much attention until the last 10 years, he says, but a good description of it was published by Gruère as early as 1838. Comby himself has encountered 104 cases; 54 in girls. In 6 cases, 2 or 3 members of the family were affected. A neurotic-gouty family history was evident in 62 cases. Preceding dyspeptic disturbances were frequently encountered as also a history of some infectious disease, but appendicitis is one of the most frequent causes: liver trouble and acetonemia are more dubious factors. In the 10 fatal cases on record fatty degeneration of the liver and certain gastrointestinal lesions were encountered, but the appendix was not examined in all. The attack comes on suddenly as a rule, the vomiting continuing for one or three days, or even from eight to ten days. Obstinate constipation is the rule with great prostration, and sometimes there is vague abdominal pain. There may or may not be fever; sometimes it is very high. Coincidence or succession of migraine in some cases is mentioned. He found appendicitis in 50 per cent. of his cases, and regards appendicectomy as the best means to put an end to this recurring vomiting. Medical treatment consists in alkalines to combat the evident acid intoxication, giving from 30 to 60 grains of sodium bicarbonate a day. In prophylaxis he advises a vegetable diet, out-of-door life and general hygiene. During an attack nothing should be given by the mouth, and lavage of the stomach may arrest the vomiting. Morphin is a valuable aid, with saline infusion to restore the needed fluids. The diagnosis has generally wavered between indigestion, poisoning, migraine, meningitis, intestinal obstruction, peritonitis and appendicitis. In 3 of his cases the vomiting recurred even after appendicectomy. In prophylaxis he has frequently derived benefit from a powder containing 0.25 gm. each of calcined magnesia, benzonaphthol and sodium bicarbonate with 0.01 gm. pulverized nux vomica. One of these powders is taken before 2 meals for 10 days and then a wineglassful of Vichy water in their place for 10 days, after which the powders are resumed. This kept up systematically seems to relieve and ward off recurrence unless the trouble is due to the appendix. A simple indigestion or poisoning rarely induces such severe and incessant vomiting. He summarizes the details of his 104 cases. The vomiting recurred every month in some, every four months or more irregularly in others. An acid and chloroformic odor of the breath just before or during the attacks was noticed in a large number of the cases. He quotes extensively from American writers, especially J. P. Crozer Griffith in *American Journal of the Medical Sciences*, 1909, cxx, 553, who also reports a case in which the attacks recurred after removal of the appendix. In 2 of the 4 cases mentioned the children succumbed.

37. **New Sign in Meningitis in Children.**—Brudzinski's previous announcement of the value of the contralateral reflex as a sign of meningitis has been confirmed by his later experience in 17 cases of tuberculous meningitis and 6 of the epidemic variety. He now announces a sign which is even more constant in meningitis than the Kernig and Babinski signs, having been encountered in all but one of 48 cases of meningitis of various etiology, and this exception was in a moribund child. He discovered the sign accidentally in testing for rigidity of the back of the neck; as he tried to bend the neck he noticed flexure movements in the ankle, knee and hip joints. In one child with pneumonia the positive findings with this neck sign cast doubt on its specific nature until further signs of meningitis developed and lumbar puncture gave issue to a purulent fluid containing pneumococci. Increased pressure on the brain is not enough alone to induce this sign as it is absent in hydrocephalus and other abnormal brain conditions.

39. **Kidney Complications of Measles.**—Biehler declares that the fact that complications on the part of the kidneys are so seldom encountered with measles is because no one thinks of looking for them. She, however, has found pyelitis or pyelonephritis in 9 out of 147 cases of measles and albuminuria in 59 others. In some cases the absence of anything else to explain the persisting high fever first led to examination of the urine with resulting discovery of the kidney complication. Nephritis was discovered in a tenth case of mild measles. All but 2 of the 10 children were girls, and the kidneys were known to have been previously healthy. The children all recovered in less than six weeks but in one case nephritis occurred again during an attack later of scarlet fever.

41. **Treatment of Epilepsy.**—Long reports 7 years' experience in treatment of epilepsy by giving bromids while reducing the intake of salt. He expatiates on the necessity for (1) careful dosage of the bromids as their action is much enhanced under these conditions; (2) exact determination of the amount of salt still permissible; (3) most appropriate form of salt-free diet, and (4) the influence of this diet on the general health. His conclusions emphasize the importance of this method of treating epilepsy as the patients bear it well and it can be kept up indefinitely without harm. In the past, some of the accidents ascribed to bromid intoxication, he suggests, may have been due to the enhancing of the action of the bromid by the patient's casually and unintentionally ingesting less salt than usual, as when, for instance, his diet included more milk. On the other hand, if he happened to eat more salted food than usual, the action of bromids being taken at the time would be correspondingly reduced. The combination of a salt-free diet with bromids given for their sedative action in other affections may prove a valuable innovation in all fields of therapeutics. Long gives the details of 4 typical cases of severe epilepsy in which this treatment was kept up for years with great benefit, the patient being under observation for more than 7 years.

43. **The Expediency of High Forceps.**—Miescher has been able to find records of 484 childbirths in which extraction was by high forceps, and by comparing the immediate and ultimate outcome he seeks to determine the relative rank of this method of delivery. The list includes 26 deliveries with normal and 25 with contracted pelvis at the gynecologic clinic at Basle, which he reports in detail. The principle for the application of high forceps, he affirms in conclusion, is that it is the last resource of expectant treatment before perforation; he prefers it in the interests of the mother to a pelvis-enlarging operation. Consequently the forceps should be applied without force, tentatively, ready to proceed, in the home, to perforation or, in the hospital, to conservative Cesarean section or pubiotomy at need. The mortality of 30 per cent. among the children should not deter as, in the home, 70 per cent. of the children are delivered alive who otherwise would have succumbed to perforation.

45. **Febrile Deliveries and Prognosis for the Puerperium.**—Wirz reports from von Herff's clinic at Basle 212 febrile deliveries, about 52 per cent. in primiparæ. The outcome of the cases was the more favorable, the more conservative the management of the childbirth. The main cause for the fever is the premature rupture of the membranes; on this depend all the other phenomena observed. The more protracted the birth after rupture of the membranes, the worse the prognosis; it may be regarded as fatal if the febrile labor extends over several days. The height of the fever is no criterion as to the ultimate outcome. A persistently high pulse rate, even with relatively slight fever, is serious ground for alarm, especially when the temperature subsides as the pulse increases. Operative interference renders the outlook still graver; it should be considered only when tympany of the uterus and other signs indicate severe infection. Under all other conditions, spontaneous delivery seems to offer the best prospects for both mother and child

47. **Predetermination of Sex.**—Schöner has had access to a parochial register which records the dates of births in 315 families for nearly 100 years, a total of 1,615 children. Comparison of the details recorded here with his own experience and results of his observation has enabled him to form a theory, based on arguments which he relates in detail, to the effect that the sex of the ovum is already decided at conception, and that each ovary produces three ova in succession, two of the same sex, the third of the opposite sex. The other ovary then takes up the task and produces in turn its two ova of the same and one of the opposite sex. The functioning ovary is tender, and this tenderness persists all through the pregnancy and even a little beyond. It is thus possible, he believes, to determine the sex of the fetus by computing the number of menstruations between two conceptions.

58 *Chronic Influenza. F. Franke.

53. **Asphyxia of the New-Born.**—Hoerder explains asphyxia of the new-born as the result of intrauterine stimulation of the respiration center by deprivation of oxygen from some interference with the circulation during the birth process. As the respiration center is thus stimulated, the fetus makes a breathing movement and this draws amniotic fluid into its air passages so that normal respiration is impossible when it finally emerges into the air. The spasmodic breathing movements that follow strong stimulation of the respiration center from lack of oxygen cause the aspirated substances to be drawn unusually deep into the air passages, as in drowning, and this is the cause and danger of asphyxia neonatorum. He warns that a sudden jet of cold water has been known to arrest the respiration even in health. Alternation of friction and dipping the child into cold and warm water are more to be advised. The stimulation from the air has also an influence, the tender skin of the new-born infant probably sharing in the respiratory process. He commends Ogata's modification of the Schultze method and Prochownik's method (the former was described in THE JOURNAL, Dec. 14, 1907, page 2044, and Volland's method, Oct. 2, 1909, page 1140), declaring that perseverance is liable to be rewarded with success even after hours. When he was a student, an infant in asphyxia was given up by the obstetrician in charge after prolonged efforts at revival had proved unavailing, but after he had left the room the students took the supposedly dead infant out of the crib to continue their practice of the Schultze swinging which they did not strive to make particularly gentle; in the hands of the third student the child was found to be alive.

56. **Treatment of Felon.**—Kofmann commends the method of incising along the tendons but never over them, reaching them from the side and never cutting into the joint if he can avoid it. He supplements this single incision with a crescent-shaped incision around the base of the nail, distant about 3 mm., cutting down to the bone. This prevents injury of the sensitive tip of the finger and deformity of the joint.

58. **Chronic Influenza.**—Franke ascribes to chronic influenza a number of common ailments which are generally regarded as pure complications and intercurrent affections, but which he thinks are due to the persistence of the influenza infection. The list includes tedious bronchitis, asthma, bone and joint affections, conjunctivitis, neurasthenia and catarrhal affections of various kinds both of the respiratory and gastrointestinal passages. The recurrence or persistence of influenza is frequently styled "mere cold," but every acute influenza, he affirms, should be regarded and treated as a serious illness and every effort made to cure it completely to prevent its persistence in a chronic form. If in any way possible, the

patient should stay in bed and not try to fight the infection, particularly if there is much prostration. In nothing else is it so important to refrain from drafts and getting chilled: the body is incredibly sensitive to these factors during influenza infection, more objectively than subjectively. The patients "catch cold" even in dressing, and in some cases every chilling is followed by aggravation of the state of the blood, aspect and general condition. In some cases he has been able to transform the ailing patient completely by housing him in a warm room for three or five months. One of his own children had *influenza* twice before the age of 2, once followed by paralysis of the legs for three months and attacks resembling angina pectoris, the pulse dropping to 60. The child did not grow robust until he was kept in the house, protected against chilling, for four or five months for two consecutive winters. He warns his *influenza patients:* "Beware of getting chilled sitting, lying or standing," but he commends exercise, warmly clad, in almost any weather. Another peculiar feature of influenza is the extreme sensitiveness of the skin to mechanical injury. Complete rest of body and mind aids materially in the cure of bone and joint and other affections of influenzal origin. Bromids are indispensable in the nervous form but iron and quinin do not benefit as the apparent anemia is really a neurasthenic pseudo-anemia; arsenic is the main reliance. He has frequently been amazed at the improvement on a mixture of 5 gm. Fowler's solution, 10 gm. tincture nux vomica and 15 gm. tincture valerian, of which 10 drops are taken in a large glass of water after meals. The dose is increased by one drop until 30 drops are being taken three times during the day. This is kept up for a month or two and then gradually reduced. Very hot brief baths are less debilitating than other forms of bathing in these cases and help in the toughening process. The raspberry tongue is characteristic of chronic influenza; the papillæ on the front of the tongue being red and swollen. A red stripe on the anterior pillars of the fauces is also characteristic during an acute attack and during acute exacerbations.

59. **Functioning of Diseased Kidneys.**—Schlayer publishes the results of experimental research which show that the elimination of certain substances is exclusively the task of the tubules or of the vessels. Salt is evidently eliminated by the convoluted tubules and the elimination proceeds undisturbed, so long as they are intact, no matter how much the kidney may be diseased otherwise. On the other hand, lactose seems to be eliminated exclusively by the vessels so that the elimination proceeds unmodified by disease of the tubules. The experiments were made with salt, lactose and potassium iodid. The latter behaved like salt in these experiments. About 150 series of researches were made on rabbits; the nephritis was induced with chromin, aloin, corrosive sublimate or uranium, to act on the tubules, and with cantharidin or arsenic to act on the vessels. The result of this research demonstrates that there are two kinds of hyposthenuria, as he calls the excretion of abnormally thin urine. When the tubules are diseased the solid elements are unable to pass into the urine. When the vessels are unusually irritable they respond to the slightest stimuli by throwing off large amounts of water. This dilutes the urine but the solid elements are eliminated as usual, only more diluted. It is thus possible to distinguish between tubular and vascular hyposthenuria.

62. **Serotherapy and Its Dangers.**—Scheidemandel discusses the condition known as anaphylaxis, allergy or hypersusceptibility, and warns that the experiences to date show the possible peril with serotherapy. It should be restricted to cases in which it is absolutely necessary, and the patient's susceptibility should be determined, with minute doses first. Before giving the serum, inquiry should be made as to whether the patient has ever used it before. Scheidemandel thinks that it is possible that curative serums derived from monkeys may be better suited for clinical use than horse serum. He reports a case of severe collapse after a third injection of antistreptococcus serum given on account of a febrile osteomyelitis of the pelvis. These anaphylactic phenomena have been observed as late as three years after the first injection.

66. **Organotherapy of Climacteric Disturbances.**—Bucura suggests the use of milk from cows in heat as a form of organotherapy of climacteric disturbances. He is theoretically convinced that such milk contains exceptional amounts of the internal secretions of the ovaries, and that it might be possible to prevent disturbances from castration if such milk were systematically taken.

70. **Duodenal Ileus.**—Weinbrenner urges that more attention should be paid to postoperative duodenal ileus as it is so easily remedied. The syndrome is apparently that of perforation peritonitis with a stormy onset, but all disturbances subside if the patient assumes the ventral or the knee-elbow position. This relieves the mechanical trouble causing the disturbances. The possibility of this mechanical ileus should be borne in mind in every case of persisting postoperative vomiting of bile.

72. **Suture of the Arteries.**—Ranzi reports four cases. They emphasize anew the importance of examining for disturbances of the circulation in every case of fracture; the trauma may have injured some vessel by a bone splinter or from thrombosis, without laceration of the vessels, or by compression from a hematoma or the vessels may have been cut in the injury. The suture of the artery was successful in all but one case in which the patient was not seen until twenty-four hours had elapsed after contusion of the arm and a plaster cast had been applied in the interim. The radial pulse was still missing when the cast was removed, and gangrene developed, notwithstanding the resection of the thrombosed portion and suture of the brachial artery. Gobiet reviews the his-

tory of the subject, mentioning that 74 cases have been recorded, including 17 of circular suture of an artery. He describes a successful case of suture of the axillary artery after removal of an arteriovenous aneurism in a young man. This makes the fifteenth aneurism operation followed by suture; the results were satisfactory in all. In another case a laceration of the popliteal artery from dislocation of the tibia was treated by resection and suture. Gangrene developed, requiring amputation, followed by smooth recovery. He thinks that this is the first case of the kind on record in which an attempt was made to save the limb after such an injury. The prognosis of this injury is very grave and if the defect is two inches long a simple suture is inadequate and the gap should be bridged by a piece of the saphena, excised for the purpose, or its equivalent.

75. **Glycosuria and Pregnancy.**—Reichenstein examined 93 pregnant women in respect to their tolerance for sugar, finding that the fact of the pregnancy seems to have a remarkable effect in reducing the limit of tolerance for sugar. A marked tendency is displayed for glycosuria, both spontaneous and alimentary, as also for alimentary levulosuria. He theorizes to explain it as the result of the action of the ovaries on the other glands with an internal secretion which normally regulate the carbohydrate metabolism, the liver, pancreas, thyroid, parathyroid and suprarenals.

77. **Treatment of Pancreatitis.**—Albrecht reports a case in which the symptoms indicated acute pancreatitis and the laparotomy revealed traces of fat necrosis near the pancreas, but the organ itself was not examined. The transverse colon was found much distended and a drain tube was introduced to form a Witzel fistula. The symptoms rapidly subsided and the patient, a workman of 39, was soon restored to health, except that a slight tendency to jaundice is apparent. Examination a year later showed alimentary glycosuria and abnormally small amounts of trypsin in the stools; these findings were accepted as indicating that the trouble the year before had been true pancreatitis. The clinical picture simulates perforation peritonitis or ileus, but the absence of increased peristalsis and of progressive vomiting turn the scale in favor of pancreatitis. The pulse, pressure and tenderness are not so pronounced as with perforation peritonitis, and the cyanosis of the face and a tendency to jaundice speak for pancreatitis. Another differentiating element is the absence of indican in the urine although positive findings do not absolutely exclude a pancreas affection. The fat tissue necrosis was of such slight extent in his case that the operation evidently had been done during the early phase of the trouble. Between the onset of the acute symptoms and the operation only five days had elapsed, and yet the patient was in such collapse that the condition seemed beyond relief, but the opening made into the intestine and drainage transformed the clinical picture at once, so that a fistula into the large intestine should be regarded as an important measure in acute pancreatitis with much meteorism. In conclusion, he urges the importance of keeping an oversight of all patients who have had acute pancreatitis. Phillips has reported that diabetes developed in 2 out of his 6 cases of chronic pancreatitis.

79. **Active Immunization Against Acne, Furunculosis, etc.**—Sellei reports good results with a staphylococcus vaccine in various staphylococcus affections of the skin. The best results were obtained in furunculosis, two or three applications arresting the affection. He describes the method of making the vaccine and its application.

81. **Hypophysis Tumor.**—Smoler reports a case in which the hypophysis tumor was readily removed by the nasal route, but the patient succumbed to pneumonia from aspiration of blood. In another case of the kind he would make a preliminary tracheotomy before attacking the tumor.

83. **Vomiting of Pregnancy and Adrenalin Therapy.**—The case reported has been previously mentioned in these columns, Rebaudi stating that a few cubic centimeters of an extract of the suprarenal capsule proved effectual in conquering previously uncontrollable vomiting which for two months had been reducing the patient to extreme debility. The adrenalin did not seem to have any injurious by-effects either on the mother or the fetus.

84. **Emptying Out the Peritoneal Sac.**—Kocks has noticed in many cases that even vigorous irrigation and swabbing are not always able to clear the peritoneal sac of all clots. Those remaining are liable to prove an excellent culture medium for germs, and they explain many of the fatalities after laparotomy. In order to clear the peritoneal sac completely, he makes a practice of turning the patient over first on one side and then on the other and continuing this until the contents of the peritoneal sac have thus been literally all poured out.

90 *Suggestions for Improved Physical Diagnosis. C. E. Waller.

90. **Physical Diagnosis.**—Waller remarks that the diagnostician has now to determine not only the presence but the character of the tuberculous process in the lung, and he presents evidence to show that the usual method of percussing symmetrical points is liable to prove misleading and that much more reliable information can be derived from study of the non-tympanitic resonance at a given point tested with percussion of varying force. This reveals the extent and the degree of dulness far better than can be estimated from percussion of symmetrical points with percussion of uniform strength. He classifies the findings as follows: 1. With light percussion: The non-tympanitic resonance is heard during the entire phase of respiration but a trifle or distinctly shortened (dulness of the first degree: D, 1); or the non-tympanitic resonance is heard only during part of the respiration (D, 2), or no non-tympanitic resonance is audible. 2. Moderate percussion: The non-tympanitic resonance is heard (D, 3); or no non-tympanitic resonance is audible. 3. Forcible percussion: The non-tympanitic resonance is audible (D, 4), or none at all is heard (D, 5). By percussing in this way, he states, it is possible to detect incipient dulness earlier than by any other method, and the findings with different investigators or after different intervals can be readily compared. The percussion findings with pleuritic effusion, etc., do not come within the scope of this method of percussion. He commences the percussion at the points where the resonance normally is particularly clear instead of in the fossa above the clavicle and the supraspinous fossa. The best point is the infraclavicular fossa, a little toward the side from the median line of the fossa, and in the back, in the infrascapular space or the "stethoscopic triangle." After study of the resonance at these points by the scheme outlined above the percussion is carried further. He discusses further the breath sounds rhythmical with the pulse, prevailing opinions in regard to the staccato and systolic breath sounds differing widely both as to their origin and their dependence on the heart action. He explains them as the result of mechanical compression at each pulse wave of the parts of the lung near the large vessels. It is not a pathologic phenomenon, not at least as regards the lungs.

When it is extremely pronounced and widespread the heart and large vessels should be examined. In conclusion, he discusses what is meant by the term "rough breathing" as used by Turban, Grancher and others, his definition being that it is not a true breath sound, but is probably due to muscular contraction and is of no importance for the diagnosis of pathologic conditions in the air passages, except as it apparently grows louder as the true breath sounds grow feebler in abnormal conditions.

91. Operative Treatment of Stenosis of Larynx and Trachea.—Uchermann's long article was one of the addresses presented at the recent international medical congress, and discusses the subject on a broad basis of personal experiences.

92. Placenta Prævia in Norway.—Kahrs has found official records of 1,505 cases of placenta prævia among 2,858,901 births since 1853 and up to 1896. The record averages 1 case to 1,200 births, with the death of 7 of the mothers and of 30 of the children each year. He tabulates the cases to show the frequency in towns and rural districts and the comparative mortality after different obstetric interventions. The maternal mortality averaged 18.3 per cent. after version; 13.6 per cent. after forceps delivery; 25 after tamponing and 77.3 per cent. with natural delivery. The mortality of the children was 58.5 per cent in the 989 cases with version; 37.7 per cent. in the 239 with forceps; 50 per cent. with tamponing, and 11.4 per cent. in the 44 spontaneous deliveries. The total maternal mortality was 12.9 per cent.; and the fetal mortality 56.3 per cent.

93. Glycerin in Pernicious Anemia.—Vetlesen has given glycerin in 2 cases of pernicious anemia according to Tallquist and Faust's suggestion that glycerin might combine with the lipoid substance assumed to be responsible for the disintegration of the red corpuscles, combining to form a harmless product. The special lipoid substance found in the anemia from intestinal parasites proved to be oleic acid, and this combines with glycerin to form triolein. Vetlesen's first case was very encouraging and in the second administration of 3 tablespoonfuls of glycerin a day, with lemon juice, was followed in the course of two and a half months by an increase in the reds from 990,000 to 4,760,000, and of hemoglobin from 20 to 90 per cent. No other drugs were given except a little antipyrin and caffein for a day or so to combat a neuralgic headache. The patient was a woman of 33, six weeks after the birth of her fifth child. During the latter part of the last pregnancy there had been some edema of the legs and albuminuria, but after normal delivery the albumin disappeared almost entirely. Five weeks later great weakness, cardiovascular symptoms, vertigo and darkness before the eyes developed, with some fever and mental hebetude by the end of the week, extreme pallor, systolic anemic heart sounds, and retinal hemorrhages, but no hypochlorhydria. The red corpuscles were increased in size and irregular in shape. In less than a month under the glycerin the hemoglobin had increased from 20 to 60 per cent., and the reds from 990,000 to 2,860,000. By the end of the two months and a half the weight had increased by nearly 20 pounds.

95. Acute Articular Rheumatism and its Complications.—Thiis reviews the experience with 288 cases during 13 years at the Christiania hospital and also with 247 cases of heart disease, 32 of chorea, 89 of chronic rheumatism, and 34 of gonorrheal joint affections to determine their connection with acute rheumatism. A second attack of the acute articular rheumatism occurred in 25.5 per cent., a third in 12.3, and a fourth in 4 per cent., while a fifth, sixth and eighth was known in from 2 to 0.4 per cent., thus a total of 45 per cent. of the patients had the disease more than once. Two-thirds were between 10 and 30 years old A preceding or accompanying infectious sore throat was noticed in 53 cases. Complications on the part of the heart occurred in 41 cases, 33 per cent. in patients under 10, 23.3 per cent. between 10 and 20, but only in 7 per cent. of 100 patients between 20 and 30 and never in the 20 patients over 50. In 113 of the 242 cases of heart disease there was a history of acute articular rheumatism, that is, in 46.5 per cent., of arteriosclerosis in 10.7 per cent., of syphilis in 9.2, and influenza in 2.5 per cent., and of scarlet fever, sepsis or chorea in from 1.6 to 1.2 per cent. Only 5 of the 32 patients with chorea had a history of acute rheumatism, but it was possible in 2 other cases, a total of 21.8 per cent. There was some cardiac defect in 31 per cent. of his cases of chorea; in 4 others the affection developed after a fright. About 50 per cent. of the chorea patients had no inherited neurotic or personal rheumatic tendency, but in the others mental derangement, alcoholism or chorea was evident in other members of the family or the parents. In one case exophthalmic goiter developed at the age of 26 after the girl had had five attacks of acute rheumatism. Vetlesen has reported 2 such cases among 43 with exophthalmic goiter, and in 8 he noticed rheumatic complications. In Thiis' 89 cases of chronic rheumatism, a directly preceding acute articular rheumatism was recorded in 14.6 per cent., and in 9 others after an interval of years. In 2 patients there were hallucinations during salicylic medication, suggesting intoxication, and another patient died. The latter was a servant maid of 27, but the exact amount of salicylate taken before entering the hospital was not known, and there were symptoms of diphtheria. Twelve of the patients with acute articular rheumatism were pregnant, and in 2 at the seventh or eighth month premature delivery occurred under the salicylic medication, but one was a syphilitic and the other had erysipelas at the time. One young woman developed urticaria five or ten minutes after taking a tablespoonful of a salicylate solution, equivalent to 15 grains.

96 *Mode of Action of Gastroenterostomy. (Gastroenterostomiens Virkemaade.) A. Pers.

October 7, No. 40, pp. 1091-1116

97 *Collective Inquiry in Regard to Cancer in Denmark. J. Fibiger.

96. Action of Gastroenterostomy.—Pers reports the results of Roentgen examination of 40 patients from a few months to six years after gastroenterostomy to determine its ultimate action. He found that the stomach emptied itself in from 10 to 25 minutes in 9 cases; in from 20 to 50 minutes in 15, and in about 90 minutes in 15. The gastroenterostomy thus answered its purpose of rapid draining away the contents of the stomach in nearly every case, and this effect was obtained whether the pylorus had previously been permeable or not. He gives typical skiagraphs of the findings and of the two exceptions in which the pylorus evidently participated in the evacuation of the stomach; in one of these there were still dyspeptic disturbances. The new opening had either become obstructed or the stomach musculature was too weak, so that the evacuation of the stomach proceeded more as under normal conditions.

97. Report of the Danish Cancer Research Committee.—Fibiger states that 1,668 question blanks were sent to medical men throughout Denmark; 144 reported that they were no longer practicing, but all the others, with 11 exceptions, filled out the question blanks with scrupulous care. Microscopic findings were mentioned in 35 per cent. of all the cases of cancer. Only 620 physicians had cancer patients in their charge on the day selected for the enquiry, April 1, 1908. Dropping a few duplicate cases, the number of known cancers in charge of physicians was 1,138 in a population of 2,650,000, that is, 0.43 per thousand inhabitants. This proportion is a little larger than is reported elsewhere, but may be due to more precise records. The proportion of cancer patients in the cities was somewhat larger than in the rural districts, three times as many uterine cancers being reported in the cities than in the rural districts, while gastric cancer is more frequent in the country. About 92 per cent. of the women with uterine cancer and 64 per cent. with mammary cancer tory of the subject, mentioning that 74 cases have been recorded, including 17 of circular suture of an artery. He describes a successful case of suture of the axillary artery after removal of an arteriovenous aneurism in a young man. This makes the fifteenth aneurism operation followed by suture; the results were satisfactory in all. In another case a laceration of the popliteal artery from dislocation of the tibia was treated by resection and suture. Gangrene developed, requiring amputation, followed by smooth recovery. He thinks that this is the first case of the kind on record in which an attempt was made to save the limb after such an injury. The prognosis of this injury is very grave and if the defect is two inches long a simple suture is inadequate and the gap should be bridged by a piece of the saphena, excised for the purpose, or its equivalent.

75. **Glycosuria and Pregnancy.**—Reichenstein examined 93 pregnant women in respect to their tolerance for sugar, finding that the fact of the pregnancy seems to have a remarkable effect in reducing the limit of tolerance for sugar. A marked tendency is displayed for glycosuria, both spontaneous and alimentary, as also for alimentary levulosuria. He theorizes to explain it as the result of the action of the ovaries on the other glands with an internal secretion which normally regulate the carbohydrate metabolism, the liver, pancreas, thyroid, parathyroid and suprarenals.

77. **Treatment of Pancreatitis.**—Albrecht reports a case in which the symptoms indicated acute pancreatitis and the laparotomy revealed traces of fat necrosis near the pancreas, but the organ itself was not examined. The transverse colon was found much distended and a drain tube was introduced to form a Witzel fistula. The symptoms rapidly subsided and the patient, a workman of 39, was soon restored to health, except that a slight tendency to jaundice is apparent. Examination a year later showed alimentary glycosuria and abnormally small amounts of trypsin in the stools; these findings were accepted as indicating that the trouble the year before had been true pancreatitis. The clinical picture simulates perforation peritonitis or ileus, but the absence of increased peristalsis and of progressive vomiting turn the scale in favor of pancreatitis. The pulse, pressure and tenderness are not so pronounced as with perforation peritonitis, and the cyanosis of the face and a tendency to jaundice speak for pancreatitis. Another differentiating element is the absence of indican in the urine although positive findings do not absolutely exclude a pancreas affection. The fat tissue necrosis was of such slight extent in his case that the operation evidently had been done during the early phase of the trouble. Between the onset of the acute symptoms and the operation only five days had elapsed, and yet the patient was in such collapse that the condition seemed beyond relief, but the opening made into the intestine and drainage transformed the clinical picture at once, so that a fistula into the large intestine should be regarded as an important measure in acute pancreatitis with much meteorism. In conclusion, he urges the importance of keeping an oversight of all patients who have had acute pancreatitis. Phillips has reported that diabetes developed in 2 out of his 6 cases of chronic pancreatitis.

79. **Active Immunization Against Acne, Furunculosis, etc.**—Sellei reports good results with a staphylococcus vaccine in various staphylococcus affections of the skin. The best results were obtained in furunculosis, two or three applications arresting the affection. He describes the method of making the vaccine and its application.

81. **Hypophysis Tumor.**—Smoler reports a case in which the hypophysis tumor was readily removed by the nasal route, but the patient succumbed to pneumonia from aspiration of blood. In another case of the kind he would make a preliminary tracheotomy before attacking the tumor.

84 *Emptying the Peritoneal Sac. (Ausschütten des Peritonealsackes.) J. Kocks.

83. **Vomiting of Pregnancy and Adrenalin Therapy.**—The case reported has been previously mentioned in these columns, Rebaudi stating that a few cubic centimeters of an extract of the suprarenal capsule proved effectual in conquering previously uncontrollable vomiting which for two months had been reducing the patient to extreme debility. The adrenalin did not seem to have any injurious by-effects either on the mother or the fetus.

84. **Emptying Out the Peritoneal Sac.**—Kocks has noticed in many cases that even vigorous irrigation and swabbing are not always able to clear the peritoneal sac of all clots. Those remaining are liable to prove an excellent culture medium for germs, and they explain many of the fatalities after laparotomy. In order to clear the peritoneal sac completely, he makes a practice of *turning the patient over first on one side* and then on the other and continuing this until the contents of the peritoneal sac have thus been literally all poured out.

90 *Suggestions for Improved Physical Diagnosis. C. E. Waller.

90. **Physical Diagnosis.**—Waller remarks that the diagnostician has now to determine not only the presence but the character of the tuberculous process in the lung, and he presents evidence to show that the usual method of percussing symmetrical points is liable to prove misleading and that much more reliable information can be derived from study of the non-tympanitic resonance at a given point tested with percussion of varying force. This reveals the extent and the degree of dulness far better than can be estimated from percussion of symmetrical points with percussion of uniform strength. He classifies the findings as follows: 1. With light percussion: The non-tympanitic resonance is heard during the entire phase of respiration but a trifle or distinctly shortened (dulness of the first degree: D, 1); or the non-tympanitic resonance is heard only during part of the respiration (D, 2), or no non-tympanitic resonance is audible. 2. Moderate percussion: The non-tympanitic resonance is heard (D, 3); or no non-tympanitic resonance is audible. 3. Forcible percussion: The non-tympanitic resonance is audible (D, 4), or none at all is heard (D, 5). By percussing in this way, he states, it is possible to detect incipient dulness earlier than by any other method, and the findings with different investigators or after different intervals can be readily compared. The percussion findings with pleuritic effusion, etc., do not come within the scope of this method of percussion. He commences the percussion at the points where the resonance normally is particularly clear instead of in the fossa above the clavicle and the supraspinous fossa. The best point is the infraclavicular fossa, a little toward the side from the median line of the fossa, and in the back, in the infrascapular space or the "stethoscopic triangle." After study of the resonance at these points by the scheme outlined above the percussion is carried further. He discusses further the breath sounds rhythmical with the pulse, prevailing opinions in regard to the staccato and systolic breath sounds differing widely both as to their origin and their dependence on the heart action. He explains them as the result of mechanical compression at each pulse wave of the parts of the lung near the large vessels. It is not a pathologic phenomenon, not at least as regards the lungs.

When it is extremely pronounced and widespread the heart and large vessels should be examined. In conclusion, he discusses what is meant by the term "rough breathing" as used by Turban, Grancher and others, his definition being that it is not a true breath sound, but is probably due to muscular contraction and is of no importance for the diagnosis of pathologic conditions in the air passages, except as it apparently grows louder as the true breath sounds grow feebler in abnormal conditions.

91. **Operative Treatment of Stenosis of Larynx and Trachea.**—Ucherman's long article was one of the addresses presented at the recent international medical congress, and discusses the subject on a broad basis of personal experiences.

92. **Placenta Prævia in Norway.**—Kahrs has found official records of 1,505 cases of placenta prævia among 2,858,901 births since 1853 and up to 1896. The record averages 1 case to 1,200 births, with the death of 7 of the mothers and of 30 of the children each year. He tabulates the cases to show the frequency in towns and rural districts and the comparative mortality after different obstetric interventions. The maternal mortality averaged 18.3 per cent. after version; 13.6 per cent. after forceps delivery; 25 after tamponing and 77.3 per cent. with natural delivery. The mortality of the children was 58.5 per cent in the 989 cases with version; 37.7 per cent. in the 239 with forceps; 50 per cent. with tamponing, and 11.4 per cent. in the 44 spontaneous deliveries. The total maternal mortality was 12.9 per cent.; and the fetal mortality 56.3 per cent.

93. **Glycerin in Pernicious Anemia.**—Vetlesen has given glycerin in 2 cases of pernicious anemia according to Tallquist and Faust's suggestion that glycerin might combine with the lipoid substance assumed to be responsible for the disintegration of the red corpuscles, combining to form a harmless product. The special lipoid substance found in the anemia from intestinal parasites proved to be oleic acid, and this combines with glycerin to form triolein. Vetlesen's first case was very encouraging and in the second administration of 3 tablespoonfuls of glycerin a day, with lemon juice, was followed in the course of two and a half months by an increase in the reds from 990,000 to 4,760,000, and of hemoglobin from 20 to 90 per cent. No other drugs were given except a little antipyrin and caffein for a day or so to combat a neuralgic headache. The patient was a woman of 33, six weeks after the birth of her fifth child. During the latter part of the last pregnancy there had been some edema of the legs and albuminuria, but after normal delivery the albumin disappeared almost entirely. Five weeks later great weakness, cardiovascular symptoms, vertigo and darkness before the eyes developed, with some fever and mental hebetude by the end of the week, extreme pallor, systolic anemic heart sounds, and retinal hemorrhages, but no hypochlorhydria. The red corpuscles were increased in size and irregular in shape. In less than a month under the glycerin the hemoglobin had increased from 20 to 60 per cent., and the reds from 990,000 to 2,860,000. By the end of the two months and a half the weight had increased by nearly 20 pounds.

95. **Acute Articular Rheumatism and its Complications.**—Thiis reviews the experience with 288 cases during 13 years at the Christiania hospital and also with 247 cases of heart disease, 32 of chorea, 89 of chronic rheumatism, and 34 of gonorrheal joint affections to determine their connection with acute rheumatism. A second attack of the acute articular rheumatism occurred in 25.5 per cent., a third in 12.3, and a fourth in 4 per cent., while a fifth, sixth and eighth was known in from 2 to 0.4 per cent., thus a total of 45 per cent. of the patients had the disease more than once. Two-thirds were between 10 and 30 years old A preceding or accompanying infectious sore throat was noticed in 53 cases. Complications on the part of the heart occurred in 41 cases, 33 per cent. in patients under 10, 23.3 per cent. between 10 and 20, but only in 7 per cent. of 100 patients between 20 and 30 and never in the 20 patients over 50. In 113 of the 242 cases of heart disease there was a history of acute articular rheumatism, that is, in 46.5 per cent., of arteriosclerosis in 10.7 per cent., of syphilis in 9.2, and influenza in 2.5 per cent., and of scarlet fever, sepsis or chorea in from 1.6 to 1.2 per cent. Only 5 of the 32 patients with chorea had a history of acute rheumatism, but it was possible in 2 other cases, a total of 21.8 per cent. There was some cardiac defect in 31 per cent. of his cases of chorea; in 4 others the affection developed after a fright. About 50 per cent. of the chorea patients had no inherited neurotic or personal rheumatic tendency, but in the others mental derangement, alcoholism or chorea was evident in other members of the family or the parents. In one case exophthalmic goiter developed at the age of 26 after the girl had had five attacks of acute rheumatism. Vetlesen has reported 2 such cases among 43 with exophthalmic goiter, and in 8 he noticed rheumatic complications. In Thiis' 89 cases of chronic rheumatism, a directly preceding acute articular rheumatism was recorded in 14.6 per cent., and in 9 others after an interval of years. In 2 patients there were hallucinations during salicylic medication, suggesting intoxication, and another patient died. The latter was a servant maid of 27, but the exact amount of salicylate taken before entering the hospital was not known, and there were symptoms of diphtheria. Twelve of the patients with acute articular rheumatism were pregnant, and in 2 at the seventh or eighth month premature delivery occurred under the salicylic medication, but one was a syphilitic and the other had erysipelas at the time. One young woman developed urticaria five or ten minutes after taking a tablespoonful of a salicylate solution, equivalent to 15 grains.

October 7, No. 40, pp. 1091-1116

97 *Collective Inquiry in Regard to Cancer in Denmark. J. Fibiger.

96. **Action of Gastroenterostomy.**—Pers reports the results of Roentgen examination of 40 patients from a few months to six years after gastroenterostomy to determine its ultimate action. He found that the stomach emptied itself in from 10 to 25 minutes in 9 cases; in from 20 to 50 minutes in 15, and in about 90 minutes in 15. The gastroenterostomy thus answered its purpose of rapid draining away the contents of the stomach in nearly every case, and this effect was obtained whether the pylorus had previously been permeable or not. He gives typical skiagraphs of the findings and of the two exceptions in which the pylorus evidently participated in the evacuation of the stomach; in one of these there were still dyspeptic disturbances. The new opening had either become obstructed or the stomach musculature was too weak, so that the evacuation of the stomach proceeded more as under normal conditions.

97. **Report of the Danish Cancer Research Committee.**—Fibiger states that 1,668 question blanks were sent to medical men throughout Denmark; 144 reported that they were no longer practicing, but all the others, with 11 exceptions, filled out the question blanks with scrupulous care. Microscopic findings were mentioned in 35 per cent. of all the cases of cancer. Only 620 physicians had cancer patients in their charge on the day selected for the enquiry, April 1, 1908. Dropping a few duplicate cases, the number of known cancers in charge of physicians was 1,138 in a population of 2,650,000, that is, 0.43 per thousand inhabitants. This proportion is a little larger than is reported elsewhere, but may be due to more precise records. The proportion of cancer patients in the cities was somewhat larger than in the rural districts, three times as many uterine cancers being reported in the cities than in the rural districts, while gastric cancer is more frequent in the country. About 92 per cent. of the women with uterine cancer and 64 per cent. with mammary cancer

had borne children. The fact that 23 of 112 male patients with gastric cancer were alcoholics, and 7 of 16 with cancer of the esophagus and 4 of 11 with cancer of the liver, suggests liquor as a causal factor, but there is no history of liquor drinking among the 91 women with gastric cancer (with a single exception) and 11 with cancer of the esophagus and 6 of the liver. The influence of heredity seemed to be apparent in 5 or 6 and possibly in 7 per cent. of all the cases. The influence of contagion also seems to be indicated in a number of others, the total reaching 14 per cent., in which there was evidence in favor of the assumption of direct transmission of the cancer. This proportion was still higher, between 14 and 20 per cent., for gastrointestinal cancers. In conclusion he appeals for closer study of the particulars in regard to the anamnesis respecting possible contagion. The collective inquiry by the Danish committee, he says, is the most valuable contribution of the kind yet presented, as over 99 per cent. of the medical men throughout the country cooperated and with zealous thoroughness.

102 Thirty-five Cases of Ileus from Mechanical Obstacle. (Inre mekanisk tarmtillslutning.) G. Ekehorn.

98. **Primary Cancer in the Lungs.**—Oerström reports 7 cases of primary cancer of the lung, all but one in the right lung. The patients were between the ages of 47 and 69. One patient had had a dry cough at night for several years and began to feel weak a year before the cough increased and slight hoarseness was noticed, after which a tendency to dyspnea soon developed with increasing debility and pain in the right chest. Transient improvement followed tapping but the cancer progressed to a fatal termination four months after the increase in the cough had first suggested serious trouble. In the second case death occurred six months after the symptoms of oppression and pain in the right chest had first attracted attention. The first symptom in the third case was hoarseness, which persisted alone for nearly a year, when increasing emaciation and night sweats developed, followed by dull pain in the left thigh and inability to stand on the left leg. Signs of a lung tumor were found and spontaneous fracture of the femur confirmed the diagnosis of a metastatic cancer. Death ensued five months after the first serious symptoms. In the fourth case death occurred eight months after the patient first noticed that her right hand was growing weak and twitching. The jerkiness increased and the arm and back of the neck became involved in the spasms, after each of which the arm felt heavy and lifeless. These symptoms gradually increased to include the entire right side. On entering the hospital the clinical diagnosis was arteriosclerosis, aneurism of the aorta and brain tumor, but autopsy revealed a primary cancer in the right lung with metastases in the brain. The case shows how a metastatic brain cancer can overshadow the entire clinical picture while the primary growth escapes discovery. In the fifth case, chills were noticed and periods of great lassitude, followed in a month by development of pain in the right chest, severe cough and slight mucous expectoration, dyspnea and emaciation. The cancer diagnosed during life was found as anticipated in the right lung after death. It was accompanied by metastases in the liver, suprarenals, peritoneum, etc., and a hypernephroma was found in one kidney. The sixth patient was a soldier of 49 dying five months after he had first noticed pains in the left side of the chest radiating later to the stomach. He lost rapidly in weight and strength, but there was no cough although the physical signs indicated malignant disease in the left pleura. It proved to be a metastasis of a cancer in the left lung which had also induced metastases in the viscera. The seventh patient was a woman of 50, mother of 12 children, who had been coughing for two months, with a little blood at times in the scanty sputum; fine hard râles were heard over the left lung. She had also night sweats, but no tubercle bacilli in the sputum. The progressive dyspnea was explained by the autopsy findings in the seventh month, revealing a primary cancer in the right lung. The pathologic anatomy of the tumors in the various cases is described in detail and the prevalence of primary cancer in the lung is discussed on the basis of published records.

99. **Tuberculous Meningitis in Connection with Trauma.**—Hedesström reviews the literature on this subject and reports 5 cases from his own experience in which tuberculous meningitis followed a traumatism in persons with a primary focus elsewhere. The tuberculous meningitis was an autopsy surprise in 3 of the cases as attention had been directed solely to the trauma. The latter had probably roused the tubercle bacilli lying latent in some primary focus elsewhere and allowed their entrance into the blood where they settled in the meninges as the point of least resistance owing to the injury from the accident to the head. All the patients had been previously clinically healthy, and the trauma was comparatively trifling, but a few days afterward slight brain symptoms developed, increasing until the patients had typical meningitic symptoms by the fourteenth to the twenty-ninth day, with death the twenty-fourth to the fortieth day, the autopsy revealing the tuberculous nature of the meningitis and the unsuspected primary focus in the lungs or bronchial glands.

THE SYMPTOMATOLOGY AND FUNCTIONS OF THE OPTIC THALAMUS*

CHARLES L. DANA, M.D.
Professor of Nervous Diseases, Cornell University Medical College
NEW YORK

SYMPTOMATOLOGY

Some years ago I wrote several papers on the subject of the bilateral temperatures in cerebral hemorrhages, and came to the conclusion that cerebral hemorrhages of any importance caused a slight rise in the temperature on the paralyzed side, a phenomenon which did not occur in acute softenings and which had, therefore, some diagnostic value. I further found that there was no particular area in the cerebral hemispheres which seemed to have definite relation to rise or fall of the bodily temperature—in other words, no specific heat center, such as physiologists seem to be able to find in experimental studies on lower animals. Pursuing a somewhat similar line of investigations as regards blood pressures on each side of the body after cerebral hemorrhages, using the Riva-Rocci and Janeway apparatus, I found that, as a rule, there was a difference of several millimeters of mercury in the two sides, there being a lower pressure on the paralyzed side than on the sound side. This unilateral fall in blood-pressure is present very soon after the attack and continues for one or two weeks. The general blood-pressure usually falls during this time, and, as it does this, the blood-pressure on the two sides becomes gradually equal, even though the hemiplegia continues; hence the drop in pressure is not due to muscular paralysis. This final equalization of pressures, however, I found did not always take place. In one patient, who had had his hemiplegia for six years, I found a difference in blood-pressure sometimes of 15 or 20 mm., the pressure being lower on the affected side. For example, on one occasion, the blood-pressure on the right side was 200 and on the left side 150. On another occasion the difference was only 10, the pressure being 160 on the normal side and 150 on the paralyzed side. This patient's hemiplegia had features which indicated an involvement of the optic thalamus. His hemiplegia was not accompanied by contractures, and the arm and fingers of the hand hung straight to the side. The hemiplegia was not very great. The patient's grip was fairly good and he could walk quite well. He had no ankle-clonus and no Babinski phenomenon. While there was no anesthesia or ataxia on the affected side, he suffered intensely from central pain, complaining of a burning and soreness all the time, as well as a great deal of tenderness and hyperesthesia on the paralyzed side. He had, however, no hemianopsia, no disturbances of the ocular muscles or of the pupillary reflexes. The hemiplegia had at first been very much more marked, and was accompanied by ankle clonus and Babinski, but this had gradually disappeared, leaving, to a great extent, only a hemisensory disorder. There was evidently, also, some vasomotor disturbance on this paralyzed side, for the hand was puffy and reddened, and the circulation was evidently sluggish. This altogether formed a fairly good syndrome of the thalamic lesion, and it led me to investigate the blood-pressure in such other cases as I could observe. So far these have been only two. In both of these there was a fairly good thalamic syndrome, with a difference in blood-pressure of between 5 and 10 mm. I have not been able to discover such marked differences in blood-pressure in other old hemiplegics who did not present evidences of a thalamic involvement. Still, this part of my investigations is not finished, and I only present these points as suggestive and worthy of further investigations.

During this time, my interest being aroused in the symptoms due to thalamic lesions, I collected three reports of cases, with autopsies, which had come under my observation at Bellevue Hospital during recent years, and, at the same time, I was fortunate in observing a patient under the care of the late Dr. Loomis, who had a hemiplegia, with thalamic symptoms, and who subsequently died. The autopsy showed a very well-defined lesion, involving the inner portion of the thalamus.

I have studied the symptoms of these four cases and collated them with the studies of three other cases in which there were no autopsies, in order to see how far the records would corroborate preceding observations regarding the symptoms of thalamic lesions. In acute lesions there are three groups of symptoms: one consisting of such symptoms as disturbance of intelligence, due to the general effects of an insult to the brain; second, a set of symptoms due to the pressure of the thalamic lesion on surrounding parts, or the involvement, to some extent, of these parts, and, third, disturbances due to an injury of the thalamus itself.

1. The general symptoms vary, naturally, very much, with the condition of the patient, and have little bearing on the question of localization. Some of my patients, for example, were alcoholic; one had a beginning tuberculosis and terminal pneumonia, and two others had very extensive general cerebral arteriosclerosis.

2. The symptoms due to involvement of or pressure on neighboring parts of first importance were those causing the hemiplegia. This is due to the clot pressing on or tearing the internal capsule, so that in almost all lesions of the thalamus there is at first a hemiplegia, with usually exaggerated reflexes and signs of involvement of the pyramidal tract. These symptoms, after a

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

longer or shorter time, pass away in great part, leaving often an almost flaccid hemiplegia. With the hemiplegia there is always some anesthesia, which involves both the superficial and deep sensibilities, so that there may be some hemiataxia as well as hemianesthesia. This anesthesia improves, but, as a rule, it does not entirely disappear, so that finally the patient is left with a sensory hemiplegia largely. The other extrathalamic symptoms were those due to involvement of the corpora quadrigemina and mid-brain. These in my cases consisted only in inequalities of the pupils and paralyses of eye reflexes. Disturbances of ocular movements and forced movements of the body, and choreic and athetoid movements, might be expected, and have been observed, but were not present in my cases. The same may be said of hemianopsia, which occurs when there is involvement of the primary visual centers, including the lateral geniculate body and posterior corpora quadrigemina or the tracts connected with these.

3. The most definite symptoms of thalamic lesion alone seem to be central pain, some anesthesia and perhaps some hemianopsia. The latter two symptoms may be caused also by a lesion that is extrathalamic. Whether vasomotor and temperature changes occur or the visceral centers can be affected is yet to be proved; but the more recent cases which I have observed seem to indicate that at least extensive lesions in the thalamic territory or zone do cause such results. The pain involves the paralyzed side only; it involves the arm and hands most, the leg and foot next, rarely the head; it is more severe in the peripheral segments of the limbs, i. e., the hands and feet; it may be very distressing and intense. It is usually different from the ordinary kinds of pain, being a sort of burning discomfort, much more distressing, apparently, than sharp or aching pains, and often making the patient's life a burden. Even when the pain is only a slight dysthesia, it seems to annoy the patients intensely. Sometimes the pain is said to be neuralgic and shooting in character. I have not noted such cases.

In all my patients with autopsies there were changes in the pupils. They were usually unequal and one or the other was rigid.

In none of the cases have I observed the so-called paralysis of emotional expression, and in none have I observed any decided explosive laughter or crying, unless there were symptoms which showed that the lesion involved more than the thalamus. The hemiplegia, in these cases, if it persisted, as it usually did, to some extent, was not accompanied eventually by any increase in reflexes or signs of involvement of the motor tract. I found, in none of them, any choreic or athetoid movements, and it seems to me that these post-hemiplegic movements are in all cases, whatever their source, more commonly developed in children and not in adults.

About the time that I was studying these cases Roussy published a very elaborate monograph on the optic thalamus and the thalamic syndrome. His work contains a very complete and admirable historical introduction. It contains the records of experiments on animals which, it seems to me, are not convincing, and are certainly far less valuable than those which have been made and are now being made by Dr. Ernest Sachs. His clinical studies and pathologic work are, however, very carefully done, and he reaches the conclusion that the thalamic syndrome, which merits to-day a place in our nosology, is characterized by, first, a slight, persistent hemianesthesia, more or less marked for superficial sensation, and, second, by a slight hemiplegia, usually without contracture, and rapidly regressive; third, by a hemiataxia, which is slight, and an astereognosis, more or less complete; fourth, by sharp pains on the hemiplegic side, which are persistent, paroxysmal, often intolerable, and not yielding to any treatment, and, fifth, by certain choreic and athetoid movements in the limbs of the paralyzed side.

Aside from the purely thalamic syndrome, we often have, as already stated, lesions which involve the thalamus and the parts adjacent, so that usually the thalamic syndrome is complicated by the symptoms of these adjacent parts. If the lesion extends well forward, we have a permanent hemiplegia, with contractures. If it is more posterior, we have hemianopsia, involvement of the ocular muscles, pupillary reflexes and forced movements.

It will be seen that the cases which I have studied tend to confirm, in a general way, the elaborate studies of Roussy. We have both, apparently, independently reached the conclusion that the old idea of the thalamus being an organ which controlled the movements of emotional expression was incorrect. It seems unlikely, also, that pure lesions of the thalamus lead to any such disturbances of emotional expression as are seen in forced laughter and forced crying. Still, I believe that thalamic lesions which extend into other areas and involve some of the associated tracts and higher reflexes do produce these phenomena.

FUNCTIONS

It would be premature in me now to discuss the extremely interesting question of the anatomic connections and functions of the thalamus. Work on this line is being carried on by Dr. Ernest Sachs with the very ingenious instruments devised by Sir Victor Horsley and Dr. R. H. Clark. The tendency of the investigations of Sachs, as well as those of Roussy, and of the comparative anatomic studies of Edinger, is to show that the thalamus is essentially only an organ for the reception and distribution to the cortex of sensory impressions, that it forms a part of the primary sensory centers for vision, hearing, smell, equilibrium and deep and superficial sensibility.

One stands almost aghast at the enormous inflow of sensory impulses which this small body must be continually receiving and distributing. The spinothalamic fibers bring up sensations from the columns of Goll and Burdach, and the anterior peduncles of the cerebellum pour its equilibrating outflow from cerebellar cortex and dentate nucleus into the thalamus. The pulvinar receives some of the primary visual sensations, and there are centers which receive impulses from the auditory and olfactory nerves. This sensory inflow is distributed to the various regions of the cortex connected with the sense of vision, hearing and smell and muscular and cutaneous sensibility. Dr. E. Sachs has shown that tracts from the thalamus pass up to the precentral convolutions, there being special fibers for the face, arm, trunk and leg centers.

The thalamus, therefore, seems really to have about the function which Meynert assigned to it thirty years ago, when he said that it was an organ which received sensations and registered them in consciousness. There is still some dispute as to whether it has efferent tracts to the cranial and spinal motor nerves, acting in this way as a reflex center of a high order. It does, however, send efferent fibers to the longitudinal bundle. There is also some question as to whether there are fibers from the cortex to the thalamus. The question whether the thalamus has centers for vasomotor and thermic regulation or for the visual organs is still unsettled. At present all we can say is that it is an enormous primary sensory nodule, acting to receive and to distribute sensory impulses probably of all kinds, but just as it is not all of the primary visual centers or of the primary auditory centers so it seems to me likely that it is not the whole of the primary center for the sensations that are poured in from the spinal cord and cerebellum.

Therefore, there would come from its injury always some sensory disturbances, such as anesthesias, ataxias, astereognosis, pains, and disturbances of vision and of the ocular movements, but these would not be complete in any direction.

In conclusion, we may accept it as a fact that there is a pretty definite thalamic syndrome which has been given above and ought to enable us to recognize thalamic lesions and thalamic lesions associated with injury to neighboring parts. This syndrome may be made much more definite and modified by subsequent investigations. It may be found, for example, that some ocular reflex disturbances always occur; the character of the sensory disturbances need careful study; also the changes in the vasomotor innervation and temperature; indirectly, through involvement of the thalamus, there may be some psychical disturbances, and in large lesions forced laughter and crying may be present. The syndrome varies somewhat according to the location of the lesion. The thalamus has a vascular supply from three different sources, and the organ can not be easily destroyed altogether by one vascular lesion.[1]

Case 1.—*Focal Hemorrhage in the Optic Thalamus.—History.*—Charles C., aged 56, colored, born in the United States, occupation, porter, was admitted to Bellevue Hospital on December 26. His father died at the age of 60, of unknown cause, and his mother at childbirth; his two brothers were living and well. The family history was unimportant, there being in it no history of rheumatism or arterial disease or alcoholism. The patient was married and had two children. He suffered from the ordinary children's diseases, and had rheumatism about five years before admission. He had had no previous attack like the present. He was moderate in his habits—in his use of tobacco and beer. There was no specific history, or evidence of syphilis about him.

Present Illness.—The patient's story was that at about 11 a. m. on the day of admission, while at his ordinary work, and feeling as well as usual, he suddenly felt a severe headache, with sickness of the stomach and vertigo. He had to stop work, and an ambulance was called which brought him to the hospital.

Examination.—When admitted he was in a semicomatose state, with a very complete paralysis of the left side, so that he could not move either arm or leg; there was also a lower facial paralysis, the tongue protruding to the left. In general appearance he was fairly well nourished, mucous membranes normal, tongue white and coated. There was a systolic apex murmur over the heart; the pulse was slow (50 per minute), regular and strong, of moderate volume, and not very high tension. The arteries were much thickened and had calcareous deposits. The temperature was subnormal, 97.4 F., in rectum. respirations 28, and there were a few mucous râles in the lungs. The abdominal organs were normal; skin moist. An examination of the urine, made the next day, and on several subsequent days, showed a specific gravity ranging from 1020 to 1025, a trace of albumin, no sugar, hyaline and granular casts during the first week, but no casts after that time. The eyes showed a pronounced arcus senilis; the pupils were unequal, left large, the right small, the left reacted to light slightly, the right not at all to light or accommodation. The paralysis of the left side was complete, as stated, involving the lower part of the face, hand and leg. Both knee-jerks were exaggerated, the left more than the right; there was no clonus or Babinski reflex. There was a slight degree of anesthesia on the left side; no hemianopsia. The patient was able to swallow and his speech was normal, except that it was indistinct, owing to the clouded mental condition. He had incontinence of urine but not of the bowels. He was too stupid to exhibit any emotional disturbances.

Course of Disease.—He vomited once about an hour after admission. He passed a quiet night, took nourishment very well, and appeared much brighter in the morning. His incontinence of urine continued the next day, so that he had to be catheterized. This incontinence continued for the succeeding week. The next day his paralysis had nearly disappeared. He could move the arm and leg, in one or two days he was able to sit up and in four or five days he walked about the wards. At the end of about a week, however, he complained of weakness and grew more dull, went to bed and did not get out of it again. He continued in bed, growing more apathetic, though restless at times, and acted in a childish and irrational manner, talking continually, trying to get out of bed, so that some of the time his feet and shoulders had to be restrained. He would move his arms about restlessly, pulling at the bedclothes and trying to pull over the table near him or to stretch out and reach the patient in the neighboring bed. Still he was able to answer ordinary questions and to talk with his children, who came to see him in the first week of his stay. At the end of ten days he developed at times incontinence of feces as well as of the bladder. The changes in the pupils disappeared, as did also most of the anesthesia and all of the exaggeration of the reflexes. At no time was it possible to get an ankle-clonus or a Babinski on the left side. At the end of the third week the patient was unable to swallow nourishment and medication, and became very weak. He at no time seemed to suffer from any disorder of the special senses, his eyesight and hearing being apparently normal. His temperature, after the initial fall, gradually rose, so that on the seventh day and again on the eleventh day it was 101. It ranged during the course of his illness about 99½. The last day of his illness it rose to 102½ in the rectum. The pulse, which was at first about 50, gradually increased until, on the fifth day, it was 60, and on the seventh day 80. It then gradually increased until it ranged about 100; respirations ranged about 26 throughout the course of the disease. He had an average of one stool a day; the urinal amounts were small, ranging from 10 to 20 ounces per day, though at times some was lost with the stools. He finally developed a hypostatic pneumonia and died on January 16, three weeks after the onset of the disease.

Autopsy.—The postmortem, made by Dr. Flournoy, showed a slight amount of tuberculosis of the apex of the lungs, and beginning apex pneumonia, on the right side; a thickening and hardening at the base of the aortic valves, and a thickening of both mitral valves, with hypertrophy of the left ventricular wall; marked atheromatous changes in the aorta, both in its thoracic and abdominal portions; very general arteriosclerosis; spleen, liver, suprarenals, and abdominal viscera normal; a chronic interstitial nephritis. The brain showed marked atheroma of the vessels at the base. The dura was not adherent. No edema was noted. The only gross lesion of the brain was a hemorrhage about 2 by 1 cm. in size, in the inner and anterior portion of the right optic thalamus, and confined to the optic thalamus, but pressing very manifestly on the internal capsule behind the germ. The posterior portion or pulvinar of the thalamus was not involved, and as this is the part which is supplied by the posterior cerebral, it is to be inferred that the vessel which was ruptured was one of the small branches of the opticostriate artery, which comes from the middle cerebral.

The localizing symptoms in this case are explained by the findings. The hemiplegia was undoubtedly due simply to pressure. The patient's mental condition was very dull, and he was inclined to sleep a great deal—a phenomenon which has been observed in thalamus lesions.

---

[1] Hemorrhages in the thalamus may come from (1) the lenticulo-optic arteries; (2) the postero-internal optic (a branch from the posterior communicating); (3) the anterior choroidal arteries; (4) a branch of the posterior cerebral, which sends also branches to the geniculate bodies and their surrounding parts. Also the arteries of the corpora quadrigemina send small branches to the thalamus. On account of this varied supply of small arteries, hemorrhages of the thalamus are smaller than those of the corpus striatum. The lenticulo-optic and the branch from the posterior communicating cause hemorrhages in the anterior and posterior parts respectively. Those in the posterior part are certainly rare. It is these which destroy the pulvinar and often neighboring parts, and cause central pain, hemianesthesia and hemianopsia.

longer or shorter time, pass away in great part, leaving often an almost flaccid hemiplegia. With the hemiplegia there is always some anesthesia, which involves both the superficial and deep sensibilities, so that there may be some hemiataxia as well as hemianesthesia. This anesthesia improves, but, as a rule, it does not entirely disappear, so that finally the patient is left with a sensory hemiplegia largely. The other extrathalamic symptoms were those due to involvement of the corpora quadrigemina and mid-brain. These in my cases consisted only in inequalities of the pupils and paralyses of eye reflexes. Disturbances of ocular movements and forced movements of the body, and choreic and athetoid movements, might be expected, and have been observed, but were not present in my cases. The same may be said of hemianopsia, which occurs when there is involvement of the primary visual centers, including the lateral geniculate body and posterior corpora quadrigemina or the tracts connected with these.

3. The most definite symptoms of thalamic lesion alone seem to be central pain, some anesthesia and perhaps some hemianopsia. The latter two symptoms may be caused also by a lesion that is extrathalamic. Whether vasomotor and temperature changes occur or the visceral centers can be affected is yet to be proved; but the more recent cases which I have observed seem to indicate that at least extensive lesions in the thalamic territory or zone do cause such results. He was too stupid to exhibit any emotional disturbances.

Course of Disease.—He vomited once about an hour after admission. He passed a quiet night, took nourishment very well, and appeared much brighter in the morning. His incontinence of urine continued the next day, so that he had to be catheterized. This incontinence continued for the succeeding week. The next day his paralysis had nearly disappeared. He could move the arm and leg, in one or two days he was able to sit up and in four or five days he walked about the wards. At the end of about a week, however, he complained of weakness and grew more dull, went to bed and did not get out of it again. He continued in bed, growing more apathetic, though restless at times, and acted in a childish and irrational manner, talking continually, trying to get out of bed, so that some of the time his feet and shoulders had to be restrained. He would move his arms about restlessly, pulling at the bedclothes and trying to pull over the table near him or to stretch out and reach the patient in the neighboring bed. Still he was able to answer ordinary questions and to talk with his children, who came to see him in the first week of his stay. At the end of ten days he developed at times incontinence of feces as well as of the bladder. The changes in the pupils disappeared, as did also most of the anesthesia and all of the exaggeration of the reflexes. At no time was it possible to get an ankle-clonus or a Babinski on the left side. At the end of the third week the patient was unable to swallow nourishment and medication, and became very weak. He at no time seemed to suffer from any disorder of the special senses, his eyesight and hearing being apparently normal. His temperature, after the initial fall, gradually rose, so that on the seventh day and again on the eleventh day it was 101. It ranged during the course of his illness about 99½. The last day of his illness it rose to 102½ in the rectum. The pulse, which was at first about 50, gradually increased until, on the fifth day, it was 60, and on the seventh day 80. It then gradually increased until it ranged about 100; respirations ranged about 26 throughout the course of the disease. He had an average of one stool a day; the urinal amounts were small, ranging from 10 to 20 ounces per day, though at times some was lost with the stools. He finally developed a hypostatic pneumonia and died on January 16, three weeks after the onset of the disease.

Autopsy.—The postmortem, made by Dr. Flournoy, showed a slight amount of tuberculosis of the apex of the lungs, and beginning apex pneumonia, on the right side; a thickening and hardening at the base of the aortic valves, and a thickening of both mitral valves, with hypertrophy of the left ventricular wall; marked atheromatous changes in the aorta, both in its thoracic and abdominal portions; very general arteriosclerosis; spleen, liver, suprarenals, and abdominal viscera normal; a chronic interstitial nephritis. The brain showed marked atheroma of the vessels at the base. The dura was *not* adherent. No edema was noted. The only gross lesion of the brain was a hemorrhage about 2 by 1 cm. in size, in the inner and anterior portion of the right optic thalamus, and confined to the optic thalamus, but pressing very manifestly on the internal capsule behind the germ. The posterior portion or pulvinar of the thalamus was not involved, and as this is the part which is supplied by the posterior cerebral, it is to be inferred that the vessel which was ruptured was one of the small branches of the opticostriate artery, which comes from the middle cerebral.

The localizing symptoms in this case are explained by the findings. The hemiplegia was undoubtedly due simply to pressure. The patient's mental condition was very dull, and he was inclined to sleep a great deal—a phenomenon which has been observed in thalamus lesions.

---

[1] Hemorrhages in the thalamus may come from (1) the lenticulo-optic arteries; (2) the postero-internal optic (a branch from the posterior communicating); (3) the anterior choroidal arteries; (4) a branch of the posterior cerebral, which sends also branches to the geniculate bodies and their surrounding parts. Also the arteries of the corpora quadrigemina send small branches to the thalamus. On account of this varied supply of small arteries, hemorrhages of the thalamus are smaller than those of the corpus striatum. The lenticulo-optic and the branch from the posterior communicating cause hemorrhages in the anterior and posterior parts respectively. Those in the posterior part are certainly rare. It is these which destroy the pulvinar and often neighboring parts, and cause central pain, hemianesthesia and hemianopsia.

There was an unusual disturbance of temperature at the beginning; it could not be inferred that the lesion here had any effect on what fever the patient had later. There were no convulsive choreic movements and no evidence of pain, either central or peripheral. The patient's clouded mental condition was one that could hardly be explained by the very circumscribed lesion. The paralysis of the bladder came on early and continued to be present, despite the disappearance of the hemiplegia. One could not certainly, however, exclude the mental condition as the causative agent in producing the bladder incontinence. There were no trophic disturbances of the body and no marked vasomotor disturbances. Whether the patient had any paralysis of the emotional movements of face, I regret to say, could not be determined. They certainly were not noticeable when the examination was first made. At that time the facial paralysis was similar to that found in ordinary hemiplegia, involving the internal capsule.

The localizing symptoms were a flaccid sensory-motor hemiplegia, the motor symptoms rapidly disappearing, leaving only sensory symptoms; the absence of exaggerated reflexes; pupillary symptoms.

The absence of central pain was, no doubt, due to the fact that the posterior portion of the thalamus was not involved, the central pain probably only occurring when the branch of the posterior cerebral, which supplies this part, is affected.

The theory that choreic and asthetoid movements are produced by lesions of the thalamus, which irritate the fibers of the internal capsule, would seem to be somewhat weakened by the facts of this case, so far as they go, for here was a lesion which unmistakably pressed directly on and lay close to the motor and sensory tract of the capsule.

The mental condition was not unlike that seen in terminal apoplectic states and might be largely due to the pressure and irritation of the lesion at first; later to toxemia and secondary degenerative changes in the brain, the result of the arterial sclerosis.

Case 2.—*History.*—Henry H., aged 64, mason, was brought to the hospital with the history of having suddenly fallen from a chair, and found to be partially paralyzed on the left side. His previous history was little known, except that he had been a hard drinker. It was not until about three weeks after this attack that he was brought to Bellevue Hospital, where he was admitted on February 21.

Examination.—He was then much emaciated, with brown, dry tongue, rectal temperature 97.6, regular but feeble heart action, no murmurs. The thoracic and abdominal organs were apparently normal, except that the liver was quite small. There was no albuminuria. There was a partial paralysis of the left side, the leg being held rather stiffly, but the tendon-reflexes were absent and there was no clonus. There was some loss of cutaneous sensation on this left side. The pupils were equal, but did not react to light or accommodation. The neck was somewhat stiff. The patient was in a semidelirious state, but slept the greater part of the time. There was incontinence of bladder and bowels. The arteries were very incompressible and atheromatous.

Course of Disease.—The patient continued in about the same condition of semicoma, with a muttering delirium, but without any fever, temperature ranging from 97.4 to 98. He finally developed pulmonary edema and died two weeks after his admission and about two months after the onset of his disease.

Autopsy.—The lungs were emphysematous; the heart was hypertrophied, with some rigidity of the valves. There was atheroma of the aorta. The liver was cirrhotic. The kidneys showed some amount of cirrhosis and parenchymatous degeneration, though there had been no albumin in the urine. The brain showed a good deal of serous effusion under the pia and in the subarachnoid space. There was an old hemorrhage, which had occurred six weeks before in the thalamus, and also quite a fresh one, which lay to the outer side of the first. The first was confined to the thalamus, the second extended into adjacent parts.

In this case the localizing symptoms were masked by the confused mental condition.

There was the rather remarkable persistence of low temperature, and the rigid pupils, the sensori-motor hemiplegia without exaggerated reflexes, were suggestive. The muttering delirium and the mental cloudiness and somnolence are best explained by the general condition of arterial sclerosis and the so-called "serous meningitis" or serous effusion which were present. He had had no alcohol for two months. The loss of reflex to light and accommodation in the pupils and absence of deep reflexes were symptoms found also in the previous case.

Case 3.—*History.*—Christina T., aged 53, Italian, personal history unknown, two weeks before admission to the hospital, was going downstairs, and when near the bottom suddenly fell forward on the floor. She was picked up unconscious and remained so for about an hour. Then she became restless and delirious, and it was noticed that she had a left hemiplegia. She was brought to the hospital two weeks later.

Examination.—When admitted the patient was in a mildly delirious condition. There was a considerable degree of paralysis of the left arm and leg, but very little in the face. There was a cutaneous anesthesia of the left side, and the reflex of the knee on the left side was absent. The thoracic and abdominal organs were normal, except that the urine showed a small amount of albumin and casts.

Course of Disease.—On the succeeding days the patient became more quiet and finally quite rational. She slept most of the time. Pupils were evenly contracted, but responded to light. The paralysis gradually improved. After about ten days she began to relapse into a comatose condition, with stertorous respiration, and four days later the coma deepened, the pulse became slow, and she died.

Autopsy.—There was found a large recent clot in the optic thalamus, on the right side. The ventricular fluid was not in any excess, but was slightly stained with blood; the clot, however, had not burst into the ventricle. The kidneys showed a chronic fibrous nephritis.

Case 4.—*History.*—The patient, a man, aged 34, was taken to the alcoholic wards of Bellevue Hospital, suffering from delirium tremens. He presented the usual symptoms of motor and mental excitement, with hallucinations. Nothing was known of the previous history. His temperature on admission was 105.4. The next day it was 105.8, and he died on the second day. During his stay in the ward he showed no evidences of any paralysis or any disturbance of nervous centers, aside from the excitement and delirium.

Autopsy.—The brain in this case showed the usual degree of congestion. There was no exudation and not much edema. On cutting the brain open a small hemorrhage was found in the middle part of the posterior third of the right optic thalamus. It measured 1 by 0.75 cm. and was about the size of a small bean. Another small hemorrhage was seen on the descending horn of the right lateral ventricle. The other organs were practically normal.

The history in Case 3 simply shows a temporary hemiplegia with residual anesthesia and absent reflex. This, so far as it goes is characteristic of the thalamic syndrome. The fourth case shows simply that a small thalamic lesion may be present and cause no severe symptoms.

53 West Fifty-third Street.

ABSTRACT OF DISCUSSION

Dr. Hugh T. Patrick, Chicago: In these thalamic lesions are the pain and anesthesia pretty well defined as to localization, that is, not quite hemiplegic, but perhaps affecting only the foot, hand or face? This point might be noted in connection with my own paper, because one of the patients whom I did not inject was sent to me by a physician who assured her that I would relieve the pain. She complained of pain particularly in the upper part of the face, not limited to the supraorbital distribution; it was not pain of trifacial neuralgia, but it was exceedingly distressing and was a constant pain which was just wearing this old lady out. She had the other symptoms of thalamic lesion; that is, she had had a stroke of hemiplegia from which she had practically recovered and still had the anesthesia. There was a little clumsiness on the one side, but practically no loss of power.

Dr. H. A. Tomlinson, St. Peter, Minn.: I have the records of three cases of unusually high temperature persisting until death, in which, postmortem, I found a spot of softening on the ventricular surface of the optic thalamus just to the outside of the pulvinar. In these cases the temperature had ranged from 105 to 107 F. for several days before death.

Dr. Julius Grinker, Chicago: In the cases of hemiplegia which are followed by pain, of the kind described, are we to infer that the lesion is always in the optic thalamus?

Dr. C. L. Dana: In Dr. Patrick's case the pain was a central one, but in the cases I have seen the pain has been in the arm and foot mainly, not all over the body necessarily, but in one case I remember the patient who was rather hemiplegic still had terrible pain in the foot and leg. In another patient it was mainly in the arm; and I can conceive that the lesion might be such as to cause pain mainly in the face.

I doubt if one can get any central pain from a brain lesion alone except from a lesion of the thalamus. I do not think there can be pain from the irritation of the sensory tract behind it unless it be perhaps in the bulb. The real serious pain at least seems to be always a thalamic pain.

TRANSMISSION OF MALARIAL FEVER IN THE CANAL ZONE BY ANOPHELES MOSQUITOES *

SAMUEL T. DARLING, M.D.
ANCON, CANAL ZONE

It is between eleven and twelve years since Ronald Ross conducted his famous experiments demonstrating the transmission of malarial fever by mosquitoes. This demonstration, it seems to me, has contributed more to the forging of the key to the control of the tropics than any other one in the annals of tropical medicine, for Ross' discovery focused the attention of the medical world on the part played by suctorial invertebrates in the transmission of infectious diseases. Knowledge of this doctrine of the insect intermediary host, coupled with Dr. H. R. Carter's invaluable observation of the extrinsic period of incubation, enabled the yellow fever commission to verify Finlay's notion about the transmission of yellow fever by stegomyia mosquitoes.

The application of these two discoveries, Ross' and Reed's, to the problems of preventive medicine by your President-elect has made yellow fever a historic disease in Panama and is surely reducing the morbidity and mortality from malarial fever to the vanishing-point.

The object of the work briefly reported here was to go over the whole subject of the transmission of malarial fever by anopheles mosquitoes. I have been guided by the work of Ronald Ross, Stephens, Christophers and James, whose investigations of malaria in India and Africa must stand as models for all future workers on this subject. In every malarial region it is a matter of importance to determine the varieties of anopheles in that region, their bionomics, the species hospitable to malaria and those which can not transmit it. The English investigators, James, Christophers and Stevens, observed that different species of anopheles had different degrees of susceptibility to malaria; certain species were natural transmitters of malarial fever, while others were rarely, if ever, found infected naturally, although it would be possible to infect them under laboratory conditions. It is important, then, to determine what varieties of anopheles are present and which ones may act as the intermediary hosts in the transmission of malarial fever; this is particularly true when the malaria-transmitting anopheles have different breeding habits from those which are not responsible for the spread of malarial fever. Various observers have published notes on the breeding habits of anopheles. It may be said that there is as much selection of breeding-places by anopheles as there is selection of feeding-grounds by fish. Trout, salmon and bullheads have their analogues among anopheles larvæ, some requiring fresh aerated water, or water containing much green algæ; others select tree-holes and the recesses of epiphytic tree-plants, such as bromelias, as breeding-places; while others preferring fresh aerated water are so adaptable that they will breed in brackish water, containing half its volume of sea-water; some species require plenty of sunlight, while other sylvan species prefer shady pools in which chlorophyl-bearing algæ are relatively absent.

The identification of mosquitoes used in these experiments has been corrected or verified by Mr. A. H. Jennings, and his identifications are being checked in the Bureau of Entomology, U. S. Department of Agriculture, Washington.[1]

Notes on the species of anophelines in the Canal Zone, their relative numbers and breeding habits, were published by Mr. August Busck of the U. S. Bureau of Entomology in May, 1908. Eleven species of anophelines have been collected in the Canal Zone. Of these eleven species the three commonest ones are *A. albimanus*, *A. pseudopunctipennis* and *A. malefactor*. *A. albimanus* is much the commonest anopheles in the Canal Zone and is the one oftenest taken in quarters and barracks, although the proportion of one species to another varies somewhat with the season and locality. In certain villages only *A. albimanus* is taken in barracks, while in other villages from 5 to 10 per cent. will be *A. pseudopunctipennis*, and at Ancon during October, 1908, 27.5 per cent. were *A. malefactor* and 72.5 per cent. were *A. albimanus*. Tree-breeding species are rarely encountered and I know of no instance in which specimens of this species have been taken in quarters. The female anopheles visits quarters to obtain blood, which is necessary for the development of her ova. When specimens of *A. albimanus* (males and females), placed in a large comfortable breeding-jar with sufficient vegetable food, such as dates and bananas, were permitted to pair, the ovaries of the females showed no development within fifteen days.

The experiments were begun in October, 1908, during the rainy season and discontinued in February, 1909, during the dry season. Mosquito larvæ were collected by sanitary inspectors at various places in the Canal Zone. On being received at the laboratory, larvæ and algæ were placed in moist jars on a table in front of a window with an eastern exposure so that they got direct sunlight for an hour or two in the morning. Predaceous larvæ were killed and removed from the breeding-tanks. A preliminary difficulty was experienced in the gradual fouling the water of the tank; this was obviated in a very simple way by passing air bubbles through the water with a Paquelin cautery bulb. In this way the water was kept fresh and the larvæ remained vigorous. After the larvæ had pupated they were placed in breeding-out tubes plugged with cotton, and after twenty-four or forty-eight hours the newly emerged mosquitoes were transferred to jars made of lantern chimneys, covered with crinoline gauze, where they might pair and be kept for biting. Females would bite twenty-four to forty-eight hours after emerging; frequently on successive and always on alternate nights for a period of at least fifteen days. The species of anopheles used were *A. albimanus, A. pseudopunctipennis, A. franciscanus, A. argyritarsis, A. malefactor* and *A. apicimacula*. These mosquitoes fall into three groups: the white hind-footed group; the uniformly colored group; and the spotted-legged group.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

[1] Dr. H. G. Dyar has since verified all our identifications save one rubbed specimen which is probably *A. apicimacula*.

A series of bitings were conducted on suitable infected patients who were carrying estivoautumnal or tertian gametes in their peripheral blood, using four varieties of mosquitoes. Out of several hundred mosquitoes used in the biting experiments, 100 mosquitoes were dissected, and of these 70.8 per cent. of *A. albimanus* became infected; 12.9 per cent. of *A. pseudopunctipennis* became infected, and none of *A. malefactor* (17 mosquitoes used) became infected, although several of the latter were purposely placed in jars with *A. albimanus* and bit at the same time persons from whom the specimens of *A. albimanus* became infected.

It is concluded from this series of biting experiments that *A. albimanus*, the common white hind-footed mosquito—an extremely hardy, vigorous, rapidly developing, adaptable mosquito—is the transmitter of estivoautumnal and of tertian malarial fever in the Canal Zone at this time. Specimens of this species infected with tertian parasites became infective between nine and eleven and a half days after the first feeding. When infected by estivoautumnal parasites, sporozoites appeared in the salivary glands as early as the eleventh day in some mosquitoes and later than twelve and a half days in others. *A. malefactor* is not concerned in the transmission of malarial fever in the Canal Zone at this time. *A. pseudopunctipennis* is only slightly concerned in the transmission of malarial fever; this appears not only from the fact that only four out of thirty-one mosquitoes under the most favorable artificial conditions became infected, but from the additional fact that relatively few specimens are taken in quarters at the present time.

The English investigators appear to have made no attempt to determine the limits of infectiousness of man in malarial fever. To me this appeared to be, if possible, worth determining, because in the discharge of patients from the hospital it would be manifestly unwise to turn a patient out, although free from symptoms yet with gametes enough in his peripheral blood to infect every susceptible anopheles mosquito that might bite him. Efforts to determine the limit of infectiousness of man were made in the following way:

In the 47 biting experiments, several blood preparations were taken fresh and for staining, at the time of the biting. Differential counts of leucocytes and the ratio between crescents and leucocytes were determined the next morning. Leucocyte counts were occasionally made at the time the blood was taken so as to check this method of estimating the crescents. In this way it was always known how many crescents were in the peripheral blood per c.mm. at the time the mosquito was infected. The next step was to weigh a number of mosquitoes before and after biting in order to estimate the amount of blood retained by a mosquito. In this way the approximate number of gametes ingested could be calculated. Again, smears were made from the midgut of mosquitoes that had a few minutes before bitten a person whose blood contained numerous gametes. From this it was found that about one-half the gametes were phagocyted by polymorphonuclear leucocytes and thus destroyed. Finally, mosquitoes which had fed but once on patients whose crescents per leucocytes had been estimated were fed subsequently on dates, and on dissection of these mosquitoes the probable limit of infectiousness was determined as being near one gamete per 500 leucocytes. From these observations, I am confident that a patient with more than one crescent for every 500 leucocytes, or 12 crescents per c.mm., is infective, and it follows that such an individual should not be discharged from treatment in that condition or should be warned or required to continue treatment. Such a person is a gamete-carrier and is a menace to a malarial community whenever susceptible anopheles have access to him.

The effect of quinin administration on the number of gametes in the peripheral blood was studied in a number of patients suffering from estivoautumnal and tertian fever by the administration of 30 grains quinin daily, either with or without iron and arsenic, and by withholding quinin and merely requiring rest from labor. In estivoautumnal infections, when there were crescents in the blood, the number was reduced by quinin, 30 grains daily, at the following rates. For example, in Experiment 17 there were:

9 crescents per 100 leucocytes on December 26
5 crescents per 100 leucocytes on December 27
5 crescents per 100 leucocytes on December 28
4 crescents per 100 leucocytes on December 30
1 crescent per 100 leucocytes on December 31
0 crescents per 100 leucocytes on January 2
0 crescents per 100 leucocytes on January 13

In Experiment 20 the crescents were reduced from 67 per 100 leucocytes to one per 200 leucocytes in twenty-five days.

In Experiment 41 crescents were reduced from 92 per 100 leucocytes to one per 100 leucocytes in fifteen days; while, on the other hand, in Experiment 6, when quinin was withheld, crescents remained constantly in the peripheral blood for twenty-three days, there being 16 crescents per 100 leucocytes on admission and 20 crescents per 100 leucocytes at the end of the period.

From this it is concluded that generous daily doses of quinin, grains 10 t. i. d., will reduce the sexual forms of the estivoautumnal parasite to a non-infectious minimum in from a few days to two or three weeks, depending on the severity of the infection.

In tertian malarial fever there is never an abundance of gametes in the peripheral blood after the disappearance of the asexual forms such as is seen in estivoautumnal infections; besides, all forms of the tertian parasite disappear from the peripheral blood within two or three days under quinin treatment and occasionally disappear when quinin is withheld.

A curious relation was observed between the average number of days that gametes remained in the blood in estivoautumnal and tertian infections when under quinin treatment, the number being about ten in estivoautumnal and three in tertian, and the average proportion of the incidence of estivoautumnal to tertian malarial fever in the Canal Zone. This might be interpreted as indicating that the proportion of cases of estivoautumnal to tertian malaria depends on the number of days that gametes are in the peripheral blood in numbers sufficient to infect *A. albimanus*, which is the host for both forms of the parasite.

The infection of *A. albimanus* and the development of malarial parasites in her midgut is not interfered with by quinin when such an infected mosquito feeds daily or on alternate days for fifteen days on patients who are receiving 30 grains of quinin in solution daily. In these instances the zygotes mature and sporozoites reach the salivary glands in the usual period.

Observations on latent malaria were made during the past dry season in several villages where the malarial sick-rate did not fall to zero and where no anopheles were breeding. On a systematic blood examination of laborers and their families, I found that 10 per cent. of men who were at work without symptoms had parasites. Three per cent. of the cases of latent malaria were of the estivoautumnal variety and 7 per cent. of the tertian variety. Among the families of Spanish and West Indian laborers the amount of latent malaria was 30 per cent. A few cases of fever would arise from this source every week, probably following some loss of resistance caused by dissipation, wetting or overheating. It is this latent malaria in every tropical community which contributes largely to the preservation of the malarial parasite and to the infection of anopheles when, after the onset of the rainy season, mosquitoes have begun to breed in numbers.

The theories of Mannaberg and Craig explain the persistence of latent malaria by the process of conjugation of two ring forms within a red blood corpuscle. During examinations of the blood, in cases of latent malaria, I have frequently seen estivoautumnal crescents which had apparently been formed by the fusion or conjugation of two ring forms, or of two pigmented forms, but I have also very frequently seen in estivoautumnal and tertian malaria red blood cells infected by two or more ring forms which have gone on to maturity without conjugation. Sometimes these contiguous parasites were of the same age, but oftener one would be a little older.

Quinin administered in latent malaria appears to destroy the ring forms only and prevents the possibility of their development into gametes. The gametes in the blood stream are probably phagocyted by splenic and hepatic endothelial cells and are not influenced by quinin directly.

The points I wish to emphasize are these:

A. albimanus, the common white hind-footed anopheles, is the host for estivoautumnal and tertian malarial parasites in the Canal Zone at this time.

A. malefactor, notwithstanding its name, does not transmit malarial fever.

A. pseudopunctipennis is only slightly concerned in the transmission of malarial fever.

In the efforts at mosquito destruction, the extermination of *A. albimanus* is of paramount importance.[2]

Patients having crescents or tertian gametes in their peripheral blood should not be discharged from the hospital, nor should treatment be discontinued until gametes have been reduced to a non-infectious minimum. The destruction and prevention of development of the sexual parasites in man is of great importance and may be accomplished (1) by appropriate quinin treatment of all gamete-carriers entering the hospital; (2) by occasional quinin treatment to destroy latent malaria; (3) by the periodical blood examination of laborers in quarters where there is a high malarial rate for the detection of gamete-carriers and latent malaria in order to carry out appropriate treatment.

Thirty grains of quinin sulphate in solution daily is an efficient dose for the purpose required.

Ancon Hospital.

ABSTRACT OF DISCUSSION

DR. JOHN A. WITHERSPOON, Nashville, Tenn.: We all know now that the malarial parasite is really carried by the mosquito. I have been especially interested in the attacks made on the anopheles in the Canal Zone and the special methods used. It seems to me that the great work in the Canal Zone, especially in carrying out the discoveries of Ross, means much for the future, not only for the preservation of life of the people, but for the natural resources of the country. It solves the problem of *what to do with the products of that country*; it solves the problem of how the Canal Zone can be peopled. Nothing could be accomplished without these important discoveries. I think the people owe a debt of gratitude not only to Colonel Gorgas, but to men like Dr. Darling and others who are working there every day. The excellent work that is being done in the Ancon hospital is a credit to any country; the work done in the Canal Zone is a credit to the nation.

DR. SEALE HARRIS, Mobile, Ala.: It seems to me that we should apply the lessons learned in the Canal Zone to our own country. The majority of us who treat malaria cease giving quinin after the patient has been relieved of his fever. In order to prevent other mosquitoes becoming infected, I think it would be well to continue the use of quinin for a considerable length of time. Note the antimalarial work that has been done in Italy in the last five years; the death-rate there from malaria has been reduced two-thirds by this crusade, which was carried on with the idea of preventing the mosquito becoming infected. After the patients were free of fever for some days, after a sufficient dose of quinin had been given to relieve the paroxysms, quinin is given in small doses, 6 grains a day, for a period of at least three months. It seems to me that in the treatment of malaria we should use exactly the same methods to prevent others from becoming infected, as with patients afflicted with yellow fever. Malaria and yellow fever are diseases, so far as their transmission is concerned, of much the same character. Both are transmitted by the mosquito. If we use the same measures in malaria as are used in Italy, I think we can reduce the number of cases of malaria very materially. In handling a patient with malaria, the first thing to do is immediately to isolate him by placing him under mosquito bar, or in a house where the mosquitoes cannot gain entrance. Individuals who have been exposed should receive prophylactic doses of quinin. The medical profession should begin an active crusade against malaria in this country. It means a great deal to us. When we consider that the number of deaths from malaria is probably 15,000 per annum and that several millions of people in the United States are affected by that disease, we realize the importance of the disease and we should at once institute a crusade against it. I am sure that such a crusade, carried out as it has been in Italy, will give results as good as have been obtained there.

Collections of Medical Books.—Our German exchanges comment with envious approval on the fine medical library of the College of Physicians in Philadelphia, with its 100,000 volumes, most of which are said to be the gifts of members. The *Münchener medizinische Wochenschrift* exclaims: "How much we can learn from our American cousins! With a few exceptions, which we gratefully appreciate, the books left by German physicians on their decease find their way to the second-hand bookstores to which they are sold for a song and the collection is dispersed, while if they were bequeathed to some medical library they would keep their former owner's memory in honor while benefiting the profession at large."

---

[2] I have since determined that *A. tarsimaculata* also transmits estivoautumnal parasites. This mosquito belongs to the white-hind-footed group and has recently been breeding in rather large numbers in brackish water near Colon.

THE VALUE OF ALIMENTARY LEVULOSURIA IN THE DIAGNOSIS OF HEPATIC CIRRHOSIS [*]

EDWARD H. GOODMAN, M.D.
Dispensary Physician to the Presbyterian Hospital; Assistant Instructor in Medicine, University of Pennsylvania
PHILADELPHIA

Any condition bringing about macroscopic or microscopic changes in an organ must of a necessity be accompanied by disorders of the normal function of that organ. On the other hand, there are some functional disturbances of the body and its organs, collectively and individually, which so far as we know are unaccompanied by any microscopic or macroscopic alterations of structure. Investigators interested in this particular field are devoting more and more attention to the functional consequence of organic disease. We are not content now simply to make a clinical diagnosis of a condition, but we demand to know what physiologic change is brought about by the morbid process we are studying. When it is recalled to what extent the literature has been enriched by the reports of investigators, in regard to testing the function of various organs, the publications pertaining to methods for determining disturbed hepatic function seem insignificant. The nervous and cardiovascular systems have been systematically studied; the lungs have received some attention; the stomach, the intestines and the kidneys are claiming their quota of experimental and clinical work, and functional tests for all are described, confirmed and constantly used by the foremost clinicians. Yet, despite the inestimable advantages which we have derived from some of these tests, we seem to know of none we can call to our assistance to aid us in diagnosing cases of functional disturbances of the liver.

Investigators there have been who claimed to have found clinical tests for such conditions, but one by one these have fallen into oblivion for want of confirmation. The following may be cited as illustrations:

The toxicity of the urine was thought by Bouchard[1] to be an indication of hepatic insufficiency. Schapiro,[2] in studying the question of prognosis in liver cirrhosis, stated that he found a more rapid output of strychnin, given in medicinal doses, in liver cirrhosis than normally. He also states that he found glycosuria followed 200 to 250 gm. of sugar given in the form of fruit preserves to cirrhotics, a fact which he did not properly interpret, and to which I shall refer again. Schwarz[3] eight years later, made some experiments based on Minkowski's observations that after liver extirpation lactic acid appeared in the urine. He gave 15 gm. sodium-lactate and determined the time of the appearance and the amount of lactic acid. Schwarz found that cirrohsis and functional disturbances did not affect the output, but that the lactic acid appeared later than normally, and concludes that it may be explained on mechanical rather than on chemical grounds.

The most marked advance on our knowledge of the subject we owe to Strauss,[4] who approached the question from three points of view:

1. Detoxicating process.
2. Protein metabolism.
3. Carbohydrate metabolism.

1. *Detoxicating Process.*—He observed an increase of fatty acids in the urine of cirrhotic patients. Munk some time before had found that the toxicity of a soap solution was two and one-half to three times as great when it was injected into the great body veins as it would be if it were injected into the portal veins, owing to the detoxicating action of the liver. Based on this report, Strauss gave 20 gm. sodium butyrate in 8 cases: 5 cirrhosis, 2 carcinoma and 1 chronic obstruction of the common duct. In 6 cases he found increase of fatty acids, in 1 of carcimona and in 1 of obstruction, no increase; but he lays no importance on this, as the same was observed in fever, lead-poisoning and diabetes. He regards the test as valueless.

2. *Protein Metabolism.*—With protein metabolism he had no definite results, and he believes that the study of the relation of urea to total nitrogen is worthless as a test.

3. *Carbohydrate Metabolism.*—This part of his study was based on the research of Sachs,[5] who, working under Strauss' direction, found that in frogs, after extirpation of the liver, there was a lessened tolerance for levulose, but not for dextrose, galactose and arabinose. Sachs made some clinical experiments and found that healthy individuals, as well as diabetics, stood levulose better than dextrose, whereas in liver diseases the tolerance to the same amount of levulose was very much diminished. In a later paper Sachs[6] showed that only the liver was able to form glycogen from levulose, the muscles having no such property, so that it was fair to assume that alteration in hepatic function would be expressed in a diminished tolerance for levulose.

Strauss followed up this very broad hint in 87 cases, 58 of the subjects being healthy as to their liver, clinically, and 29 hepatic cases. Of the latter, 26, or 90 per cent., showed levulosuria, while of the healthy subjects 6 showed levulosuria, giving a percentage of 10. Strauss thinks that this 10 per cent. error—one might call it—may possibly be no error, as there was no way of knowing, apart from clinical study, whether there was any latent disease of the liver or not. In fact, 2 subjects were drunkards, and suffering from obesity and gout; 1 had pneumonia (Rosenberger[7] found levulosuria to occur quite frequently in this condition) showed chronic fever, 1 anemia from gastric hemorrhage, and 1 had some hepatic congestion secondary to mitral stenosis.

In the cases of liver disease not showing levulosuria 1 was atrophic cirrhosis with severe diarrhea interfering with absorption of levulose; the second was acute cholecystitis of two days' duration; and the third was a cyst of the liver.

Furthermore, Strauss found two cases of diabetes showing levulosuria, which is remarkable, as ordinarily diabetics excreted more dextrose after levulose ingestion.

Unlike most observers advancing a new idea, Strauss says that not too much weight should be placed on the test alone, but *that a final diagnosis should be made* only after careful weighing of the data derived from clinical and laboratory examinations. He made eight observations with 150 gm. cane-sugar and found once glycosuria, four times levulosuria, once saccharosuria and two negative.

In 20 liver cases he found alimentary dextrosuria but once, which is in marked contrast to the French observers, who found it quite a usual occurrence. This discrepancy is best explained by the fact that these men used cane-sugar as a test instead of dextrose (see Schapiro[2]). DeHaan[8], in fact, reported 29 cases studied with regard to the assimilation of glucose and found 18 positive and 11 negative, but his own statement of having used 150 gm. of cane-sugar, and only in doubtful cases having recourse to the polariscope, robs his paper of any scientific value. Lépine[9] shares this view, and in his article he contributes one case of liver disease showing alimentary levulosuria.

Bruining[10] studied 21 hepatic cases with levulose, saccharose and glucose. Of the 12 cases studied with levulose, he found 10 (all cirrhosis) positive and 2 negative. Of these two, one was carcinoma of the stomach and liver, with absence of free hydrochloric acid and much lactic acid, which he thinks interfered with absorption of levulose; the other case was one of cirrhosis. Here, then, in 11 cases of cirrhosis he found 10 positive with levulose, or 90 per cent., corresponding exactly with Strauss' figures; and Bruining lays great stress on the importance of this test. With saccharose, it might be stated, he got 13 positive glucose reactions. He hints at the future possibility of diagnosing liver diseases by the way various sugars are utilized, and reports cases, one beginning cirrhosis, one of catarrhal icterus, and one in which there was no alimentary glycosuria or levulosuria, but after saccharose there appeared glycosuria in all three. He does not explain this apparently strange phenomenon.

Baylac and Arnaud[11] in the same year at the French medical congress, held in Toulouse, made a report on the clinical value of alimentary levulosuria, based on the study of 23 liver cases. Of these 21 showed levulosuria, or a percentage of 91 positive reactions. Of 20 cases presenting no symptoms referable to the liver, they found alimentary glycosuria in 7, or a percentage of 35, which is in marked contrast to the 10 per cent. of Strauss. Baylac and Arnaud guardedly add, that as these apparently liver-healthy cases occurred in hospital patients, it may be that there was some derangement of hepatic function, which would account for some of the reactions.

Landsberg[12] the next year gives his experience with 21 cases of liver disease, only 9 of which or 43 per cent. gave a positive result.

TABLE 1.—LEVULOSURIA IN 21 HEPATIC CASES (LANDSBERG)

Carcinoma	4	1
Cirrhosis	11	4
	2	2
	1	0
	1	0
Chronic obstruction of common bile-duct	2	2
	21	9

To prove his point regarding the futility of levulose as a test, he gave levulose to seven healthy persons. He obtained positive results in four, and concluded that Strauss probably took far-advanced cases for his series, in which a collateral circulation had been established, and that in this way there was rapid entrance of levulose into the blood and urine. On these seven cases he makes the rather bold assertion that as the test is positive in health, it has no value clinically, adding that he believes idiosyncrasy plays more of a rôle in alimentary levulosuria than does functional disease of the liver.

Although hardly bearing on this subject, an observation of Samberger[13] has some significance. Briefly stated, Samberger endeavored to prove that the urobilinuria seen so often in syphilis was of hepatic origin, and selected as his vehicle levulose as recommended by Strauss, with results in accordance with Strauss, Sachs Bruining and others, i. e., urobilin was present in those cases which showed levulosuria.

In 1904 Chajes[14] collected all reports on alimentary levulosuria published up to that time, adding 21 normal cases, showing only one positive levulose reaction. He includes in his table 16 cases published by Ferannini with 11 positive reactions or 69 per cent. Of 84 reported cases of clinically diseased livers, Chajes found 86 per cent. showing alimentary levulosuria; of 99 sound as to their liver, 15 per cent. showing alimentary levulosuria. He concludes the former is about the percentage of alimentary levulosuria.

Von Halász[15] criticizes Strauss' work, as he thinks that the patient might have had a low assimilation limit for all sugars, but he confirms Strauss' observations and those of other writers. Von Halász thinks the test of great service in deciding between cirrhosis and other conditions, and states that normally 100 gm. levulose rarely causes levulosuria; a positive result therefore suggests a diffuse and consequently severe disease of the liver, especially indicative of cirrhosis.

The method of examination adopted in this series was as follows: No food was given the patient after the evening meal. The patient voided his urine at a stated hour the next morning, after which, on a fasting stomach, he was given 100 gm. of levulose dissolved in 500 c.c. tea or water according to taste, the whole amount being taken within fifteen minutes. At the termination of each hour thereafter, for four consecutive hours, the urine was collected in four separate bottles, after which breakfast was eaten. It was impossible in some instances to obtain urine each hour, in which case collections every two hours had to be resorted to. Each specimen of urine, including that passed before the beginning of the test, was examined separately by the Fehling, Nylander, Seliwanoff, and fermentation tests, and the combined urine with the exception of the urine before the ingestion of levulose, by the above tests, and in addition by Rosin's method and by the polariscope. As the number of cases increased the spectroscopic examination was omitted. Despite the criticism lately directed against the Seliwanoff reaction by Borchardt,[16] I regard the test as a very useful one, and so far in my experience the disturbing factors mentioned by him have not been met with. Reliance was not placed on this reaction alone, and the presence of levulosuria was accepted as certain, only when there was reduction of the Fehling's and Nylander solutions, fermentation with yeast, a positive Seliwanoff test, and left rotation with the polariscope.

In performing the Seliwanoff test care must be taken not to confuse the rose tint obtained with many urines by boiling with hydrochloric acid, with the typical color reaction due to levulose. In the first instance the shade of red is very light, and fades away entirely on standing or on cooling, while the color in the latter case is a dark magenta red, clouding the entire specimen of urine and deepening on standing or on rapid cooling. The color due to levulose persists for days and there is deposited on the bottom of the test-tube a dark red precipitate.

The cases reported in this paper number thirty-two, and most were seen in the private practice of my chief, Dr. Musser, and in his wards at the University and Presbyterian hospitals. Additional cases were furnished me by Dr. Alfred Stengel, Dr. James Tyson, Dr. D. F. Woods, Dr. E. J. G. Beardsley, Dr. J. H. Musser, Jr., Dr. W. Taylor Cummins, and Dr. M. Solis-Cohen, to all of whom I wish to acknowledge my great indebtedness.

In the first ten cases the tolerance for glucose and saccharose in addition to levulose was tested, but this necessitated so much inconvenience on the part of the patients that it was omitted in the remaining twenty-two cases. I believe, nevertheless, that in all instances in which alimentary levulosuria can be demonstrated, the tolerance for glucose and saccharose should be determined, since there may be, in certain individuals, a normally low assimilation limit for all sugars.

In hepatic disease, after 100 gm. of levulose, the sugar usually appears in the second-hour specimen, after which time it either varies in degree or is absent entirely from the succeeding portions of urine. Strauss has already observed this phenomenon. The appearance of levulose is tardy and of short duration in cases in which the liver is but moderately affected; it is, however, rapid, intense and prolonged in cases of profound alteration, so that alimentary levulosuria may perhaps be regarded as an early symptom of hepatic disease (cf. Baylac and Arnaud[11]).

I was unable in the majority of instances to confirm the diagnosis by postmortem examinations, so it was impossible to control the extent of the hepatic lesion, but judging from the clinical course of the individual cases, I believe the inference to be drawn from the early or late appearance of levulosuria, as stated above, is correct.

As will be seen from a study of the table, all of the cirrhosis patients exhibited alimentary levulosuria, the early appearance coinciding with severe disorders and the tardy appearance with the clinically mild affections.

One case (No. 3) of marked fatty degeneration (autopsy) showed levulosuria in the first hour.

All of the six subjects of hepatic enlargement due to chronic passive congestion assimilated 100 gm. of levulose easily. In these cases the tolerance was of considerable assistance in arriving at a proper diagnosis.

One patient with ovarian cyst (No. 26; operation) had certain symptoms of cirrhosis, but showed no alimentary levulosuria, and at operation the liver was found to be apparently healthy.

Levulose was given by mistake to the diabetic patient (No. 22) instead of to another patient in the same ward. There was a marked intolerance, which is the more remarkable as diabetics are supposed to utilize levulose well (Külz,[17] etc.).

Alimentary levulosuria was present in one case (No. 27) of catarrhal cholangitis in which a cirrhosis could not be excluded.

The one patient (No. 31) with supposedly syphilitic cirrhosis utilized levulose perfectly. The clinical diagnosis was at first carcinoma of the liver, but was later changed to the one given in the table.

Patient 32 (carcinoma of the gall-bladder) excreted levulose in the last two hours following ingestion of the same.

TABLE 2.—LEVULOSURIA IN 32 PATIENTS
(100 Gm. Sugar Administered in Each Case)

SUMMARY

DIAGNOSIS.	TOTAL.	POSITIVE.	NEGATIVE.
Cirrhosis	20	20	0
Cirrhosis (?) Syphilitic	1	0	1
Fatty [illegible]	1	1	0
Chroni [illegible]	6	0	6
Catarr [illegible] (?) ..	1	1	0
Carcinoma of Gall-Bladder..........	1	1	0
Ovarian Cyst	1	0	1
Diabetes Mellitus	1	1	0
Total	32	24	8

Percentage Positive Reaction.............................75
Percentage Positive Reaction in Cirrhosis...............100
Percentage Positive Reaction in Chronic Passive Congestion.. 0
Percentage Positive Reaction in Disease of Liver, Bile-Ducts and Gall-Bladder 97
Percentage Positive Reaction in Non-Hepatic Disease 12.5

CONCLUSIONS

1. Alimentary levulosuria is almost a constant phenomenon in cirrhosis of the liver.

2. The early or late appearance of levulose may be regarded as a sign of severe or mild hepatic disease.

3. Alimentary levulosuria is a useful aid in diagnosing between cirrhosis on the one hand and chronic passive congestion on the other.

4. A study of the hepatic function with glucose and with saccharose in addition to levulose is to be desired, inasmuch as there may be an individual intolerance to carbohydrates.

5. While not indicative of any specific organic lesion of the liver, alimentary levulosuria is most frequently observed in cirrhosis.

248 South Twenty-first Street.

[17] Külz: Quoted by von Noorden, Handbuch der Pathologie des Stoffwechsels, 1907, ii, 53.

ABSTRACT OF DISCUSSION

Dr. De Lancey Rochester, Buffalo: Did Dr. Goodman find the reaction positive in cases of mixed cirrhosis and passive congestion?

Dr. J. R. Williams, Rochester, N. Y.: I have attempted to examine some cases in the way described by Dr. Goodman, with unsatisfactory results. Investigations of this sort may easily be carried on in an endowed hospital, but sometimes they are not practicable in private practice. For example, levulose costs about 80 cents an ounce, making the cost of a single examination about $2.50, obviously a prohibitive cost to the general practitioner. I have attempted to carry out the test using honey instead of levulose; honey contains approximately 50 per cent. of levulose. My experience with it is too limited, however, to enable me to express an opinion as to its value.

Dr. Edward H. Goodman, Philadelphia: It was impossible in my series of cases to control the clinical diagnosis by autopsy, so I can not say just how extensive the hepatic lesion was. I obtained levulose from Schering & Glatz of New York, one pound costing $1.60.

WATER CONTAMINATION ABOARD SHIP AND ITS PREVENTION

J. O. COBB, M.D.
Surgeon, U. S. Public Health and Marine-Hospital Service
MILWAUKEE

There are four methods of supplying drinking-water aboard ship. The first is the storage of the water in tanks and barrels which have been filled over the side from some regular supply, such as a water-boat which has run alongside. By the second the water is pumped in, or otherwise forced into the tanks, through a hose, from a city supply, over the side. By the third method the ship takes water in midstream, or when out in the lakes, by pumping through the sea-cock. The fourth method is to condense the drinking-water from steam. It sometimes happens that a fifth method of obtaining drinking-water is used by the crew, as, for example, when the ship is lying in fresh water it is common practice for the men to haul a pailful of water over the side, as this is cooler than the water stored in the tanks or barrels.

Of all the methods, it is readily seen that there is only one which can be relied on for purity, namely, the drinking-water from the condenser. All other sources are dangerous to a greater or lesser degree. Especially is this true at the present time, when it is asserted that our Great Lakes have sewage contamination several miles from shore, and most of our great shipping centers have dangerous water-supplies. It is not a surprising statement, then, that seafaring men have considerable typhoid on the Great Lakes. That some of these cases of typhoid are contracted on shore, is probably true, but that most of them originate aboard the boats, from contaminated water, is too evident a fact to be disputed. And this contamination of the water on shipboard is the result of faulty construction and a reckless disregard of sanitary principles, by all the vessels on the Great Lakes, whether private or owned by the government.

I know of no steamer on the lakes that uses a condenser; nor do I know of any boat, of any description, that takes drinking-water over the side except when laid up in the winter. It is, then, fairly safe to say that all drinking-water used aboard vessels on the lakes, for the crews and passengers, is admitted to the boats through the ordinary sea-cocks. And if this is true, then passengers and sailors are constantly drinking water which has passed through pipes that have been lying in sewage while the ship was in port. All water used aboard, for whatever purposes, is pumped through the sea-cocks which perforate the shell of the ship in the bottom, as indicated by the arrow in the diagram, which represents a cross-section of a ship, the sea-valve, pony-pump and pipes to drinking-tanks. Now suppose that valve A is kept closed when not in use—which is never the case except when the boat is laid up for the winter—then when the ship lies in the Chicago River, say, all that portion of the piping and sea-cock, from the bottom of the boat to valve A, stands filled with sewage, or Chicago River water, which is the same. But let us go farther: Suppose that the boat is loaded down so she lies in the water to the depth indicated by B, then the river-water would rise through the sea-cock to the level of B at C. From the sea-cock to the pony-pump is a long stretch of pipe in most steamers, and as the pony-pump is constantly in action to maintain the pressure in the various pipes, and to feed the boilers, it is plain that all this section of pipe is filled with sewage all the time that the boat lies in foul water. It is not hard for one to picture the scum and deposits which form on the inside of this portion of the piping from the sea-cock to the pump; and even though the drinking-tanks are not filled until the ship is well out in clear water, and *not until the* water has been forced through the sea-cock and overboard, until it comes through clean (?), still the very thought that one is drinking water which has passed through a pipe which has but a few hours before been standing full of sewage in which macerated animals and solid fecal matter are churned into solution is, to say the least, just short of nauseating. It is quite certain that the sea-cock and the pipes leading to the drinking-tanks are coated with slime and vegetable growth in which there surely must be the bacterial life common to sewage.

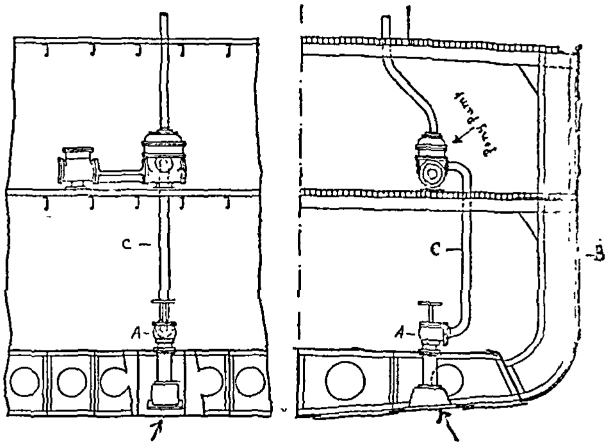

Diagram of a ship, showing method of supplying drinking-water on shipboard; a, valve to shut off river-water; b, c, level to which river-water may rise when boat is loaded down. The diagram shows, on the left, a section taken fore and aft, and, on the right, across the hull.

On certain steamers the water-bottoms are filled through the sea-cocks, and the big iron ore steamers run alongside the docks and as the ore is unloaded the water is let in to trim ship regardless of where the boats are lying. If the boat is lying in the Chicago River, or South Chicago, it makes no difference, for this water is run into the water-bottom, just the same, sewage and all. When unloaded the ship clears for another cargo, holding this water in the bottom, or *pumping it overboard,* as the exigencies of the weather permit, and when the drinking-tanks need filling, a valve is opened, and the tanks filled through the very selfsame sea-cock that was used for filling the bottom with sewage. Clearly the drinking-water for the tanks should not be pumped through the same pipes through which millions of gallons of sewage have just been pouring. It is probably true that flushing these pipes when in clear water does wash out most of the bacterial content which might otherwise cling to the vegetable growth in the pipes, but from any point of view it is absolutely disgusting to think of drinking water which has been pumped through a pipe which in the last few hours has been filled with Chicago or Milwaukee sewage.

The vessels from which the U. S. Public Health and Marine-Hospital Service receives most of its typhoid patients are the passenger boats with short runs. The main reason for this is that these boats lie in the river half of the time, and their pipes are, therefore, more contaminated than those of other ships, and there are greater chances of carelessness, such as leaving open the valves when entering the rivers, etc. It is true that the drinking-tanks are not filled until the boat is well out in clear water, and then some one opens the lateral to the drinking-tanks and lets it run until the tanks are filled. And frequently this valve is left open after the boat has entered the rivers, and the tanks are filled with sewage. If the captain discovers this carelessness, the tanks are immediately emptied and cleaned, but it must often be the case that the men or junior officers who are responsible for such a mistake will keep the matter quiet for fear of reprimand.

The drinking-water is pumped into iron tanks; these are supposed to be cleaned out several times a year, but it is a fairly safe guess that investigation would show that many of them have not been even fairly well cleaned more than twenty times in twenty years. That they are ever thoroughly and safely cleaned is impossible, as any one can easily convince himself of by a personal examination. It is admitted by every well-informed person with whom I have discussed the matter that these tanks become very foul, and are lined inside with vegetable growth and a thick slimy deposit. That typhoid bacilli get into these tanks at various times, in greater or smaller quantities, and that these same bacilli multiply on this fine medium, would seem to be a safe assertion.

Not a few times has the fact been noticed by officers of the Public Health and Marine-Hospital Service that some one particular vessel was sending an unusual number of cases of typhoid to hospital, and when conditions were looked into carefully it has always been found that there was carelessness and lack of sense and cleanliness on the part of the ship's officials. But the prime fault is one of construction, for it is impossible to guard against carelessness in this particular. In the first place, a general pipe system which lets water into the water-bottom, and to the boilers and the sanitary tanks, and the tanks for drinking-water, and through which the decks are flushed down, is a dangerous system.

I have the statement of captains to the effect that it has happened several times that vessels have come to their docks in Chicago or Milwaukee rivers with their drinking-tanks overflowing with dirty water from the rivers, because some careless person has left the valve open, and the constantly working pony-pump has kept pumping water into the tanks after the ship has entered the foul rivers. There is still another method by which the drinking-tanks can be fouled, and that is by leakage past a poorly fitting valve. The fire-drills aboard ship are most often held while in port; and almost all deck washing is done while lying at the wharf. The pony-pump is constantly running, but during fire-drill, and washing down deck with the hose, the big pump is turned in and the greater pressure in the pipes probably causes a certain amount of leakage into the drinking-tanks, past valves which may not be properly seated. This is probably a common occurrence on most boats.

All water aboard ship, for whatever purposes, must first pass through the sea-cock and pipes leading from it, and it must be alarming for one to discover, while a passenger on these vessels, many of which are floating palaces, that he has been drinking water which was introduced into the ship through pipes smeared on the inside with sewage. It cannot be clean, cannot be free from bacterial life and fecal matter. Surely no man would dare say that such water was clean and free from danger.

There are but two practical methods to avoid this contamination. One is to disconnect the drinking-tanks from the other pipes, so that it would be impossible to fill them with foul water accidentally. Then it would be necessary to drop a pipe over the side when out in clear water, and pump the water into the tanks. All the officers with whom I have discussed the matter think that this method would also be objectionable because some one would forget to haul in the pipe that was over the side. In the second method, and the only reliable way to obtain absolutely pure water, is to condense it, as is done by ocean-going steamers. It could be installed on any steamship with comparatively little expense.

403 Iron Block.

LOCALIZED SUBPHRENIC TUBERCULOSIS

EXCISION OF THE TUBERCULOUS MASS; RECOVERY; FREEDOM FROM RELAPSE AT THE END OF TWO YEARS *

CHARLES A. POWERS, M.D.
DENVER

Patient.—Mr. X., a man of 28, came to Colorado in the spring of 1907 with a moderate tuberculous invasion of both lungs. His home was in Boston, and for some months before leaving there he had suffered with pain and discomfort in the region of the gall bladder. A diagnosis of gall-bladder trouble had been made by two physicians and this was confirmed by Dr. Swan of Colorado Springs, through whose kindness I saw the patient. When I saw the young man with Dr. Swan in the latter part of April, 1907, I found him fairly well nourished; his chest trouble was in apparent arrest, he was without fever, he had a good appetite and was possessed of a fair degree of general strength. The pain and discomfort in the region of the gall bladder had recently become more marked. He had had no jaundice; he had not suffered acute pain, but the dull pain and constant discomfort had become a marked and disturbing factor in his daily life. The pain was apt to come on at night and keep him awake.

Examination.—The abdomen was found to be soft; there was no local rigidity. There were no evidences in the region of the appendix. There was moderate tenderness on deep pressure at the site of the gall bladder and this tenderness was constant. This was about the only symptom presented. The diagnosis of probable gallstones was concurred in and operation advised.

Operation.—At St. Luke's Hospital, in Denver, May, 1907; ordinary gall bladder incision. Careful inspection and palpation revealed nothing abnormal in the gall bladder or bile ducts. The cecum and appendix were explored and found to be normal. At about the middle of the liver there were adhesions between it and the anterior abdominal wall. These adhesions were not very dense and were broken through. Small, apparently tuberculous nodules were seen on the upper surface of the liver. On drawing the liver down a caseous mass about as large as the bowl of a dessert-spoon was found between the middle of the upper surface of the liver and the diaphragm and involving both. This was excised with some difficulty and its bed scraped and mopped with carbolic acid and alcohol. Moderate hemorrhage was checked by packing. Outlying nodules were excised. Free gauze packing was placed between the liver and the diaphragm. The remainder of the wound was closed.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixtieth Annual Session, Atlantic City, 1909.

The tissue removed was sent to Dr. J. A. Wilder, professor of pathology in the University of Denver, who pronounced it tuberculous.

Postoperative History.—The patient made a smooth convalescence; his sinus became permanently closed at the end of ten weeks. He has had no further trouble in the region of the liver. In February, 1908, he developed moderate appendiceal symptoms and a somewhat thickened appendix was removed, which on pathologic examination was pronounced tuberculous by Dr. Wilder. Since then the patient has had no abdominal symptoms whatever. I examined him recently, two years after the operation on the liver. His lungs are in good condition; his weight, strength and appetite are good; he feels well and enjoys life. There is no hernia at either scar and aside from the scars themselves there are no abdominal evidences. There is no evidence to be discovered of tuberculous peritonitis in any portion of the abdomen. His digestion is good; he has no discomfort.

We have in this case a localized subphrenic tuberculosis. Thorough excision of the tuberculous area was followed by healing. Two years after operation there was no evidence of relapse.

A thorough search of medical literature, in which quest I have had the kind aid of Dr. F. Robbins of New York, fails to reveal a definitely similar observation.

Eisendrath[1] reports a case of general tuberculous peritonitis with a localized subphrenic collection of fluid. Michaux[2] makes a somewhat similar observation. In his case the patient's illness began abruptly with severe dyspnea under the picture of pneumothorax. There were no gastrointestinal symptoms. Edema existed on the right side of the chest, the abdominal wall and the legs. There was a high fever. An incision along the costal arch served to evacuate gaseous pus and opened into a large cavity, reaching as far as the third rib. The operation was followed by marked improvement. The edema diminished, but subsequently an uncontrollable diarrhea developed and the patient died one month after the operation. The autopsy showed the presence of dry tuberculous peritonitis which had given rise to the formation of a subphrenic abscess.

Consideration of subphrenic abscess as a complication of an intrathoracic affection is of interest. According to Archibald,[3] this complication is extremely rare. Among 447 cases compiled by Maydl (1894), Grüneisen, and Perutz, only 21 owed their origin to this cause; including 6 instances of empyema after pneumonia; 7 instances with an unknown source of infection; 1 instance of pulmonary abscess; 2 instances of pulmonary gangrene, and 1 instance of tuberculosis. In the cases compiled by Maydl prior to 1894, with a singe exception, there was invariably found a perforation of the diaphragm. This was not demonstrable in the later cases, treated by operation, showing that the diaphragm is only gradually destroyed, later, at one or more points, as the result of the prolonged contact with the pus.

The mode of passage of the infection from the pleural to the subphrenic cavity is of interest. Küttner[4] seeks an explanation in the course of the lymph current, which was demonstrated by him through careful experimental injections. The lymph channels of the parietal pleura and peritoneal serosa communicate with those of the diaphragm, and in the diaphragm itself exist many perforating lymph vessels, not only in the direction from the peritoneum to the pleura, but also in the opposite direction. According to Burkhardt, the bacteria penetrate through the membranes and muscles by active growth instead of by passive transportation. It is possible that the metastasis is caused in either fashion. This work of Küttner has special reference to the transmission of chronic inflammatory processes from one of the two large body-cavities to the other. Küttner discusses, in the first place, tuberculosis of the serous membranes. He quotes Tilger,[5] who examined the autopsy material of the Geneva Pathologic Institute in regard to the question as to whether tuberculous peritonitis can infect the pleura by way of the diaphragm. Among forty-nine cases of extensive tuberculosis of the peritoneum, he found the pleura to be affected in thirty cases. In almost all of these, however, the pleurisy had originated independently of the peritonitis, or a chain of tuberculous lymph glands could be followed from the abdominal cavity to the thoracic space. It was only in three cases that the pleurisy had been positively transmitted from the peritoneum through the diaphragm. In one instance the peritoneal tuberculosis had led to an affection of both pleuræ; in the other two cases the right pleura alone was infected; here the process was not tuberculous in character, at least not microscopically, and Tilger assumes that only the purely inflammatory factor of the tuberculous peritonitis was transmitted through the diaphragm to the pleura. He regards it as probable that propagation in both cases took place through the lymph vessels of the diaphragm. Tilger thinks that this assumption is favored by the right-sided location of the pleural disease in both cases (relations between the lymph vessels of the liver and the right pleura). It follows, according to him, that the perforating lymph vessels of the diaphragm do not play a very important part in the primary tuberculosis of the serous membranes, but that tuberculous peritonitis and pleurisy should almost invariably be regarded as equivalent affections, arising on an identical basis (polyserositis of Italian authors).

In a general way it may be said that certain clinical cases, otherwise difficult of interpretation, may be explained in a similar manner by the perforating lymph vessels of the diaphragm, which traverse the diaphragm in the direction from peritoneum to pleura and *vice versa,* establishing numerous communications between the two large body-cavities and even providing for their relations with remote regions.

An isolated observation by Muck[6] is as follows: The patient presented bronchial bruits over the lungs and had a slightly febrile temperature. There were no other symptoms suggestive of tuberculosis. Death occurred as the result of exhaustion; at the autopsy old tuberculosis was found in the left apex and a cavity in the right apex; there was a broken-down focus in the right lower lobe. A subphrenic abscess, probably tuberculous, though not microscopically examined, was demonstrated on the right side.

Cornet[7] considers that tuberculous changes in the liver as a sequel to pulmonary phthisis are uncommon. The liver is most frequently affected in general miliary tuberculosis, under the formation of disseminated miliary tubercles, apparently not uncommonly immediately before the death of consumptive individuals. Localized tuberculosis of the liver often appears under the picture of enormous isolated, softened, tuberculous ulcers (Orth, Simmonds, Zehden, Wagner, Clement).

Hepatic tuberculosis originates by the hematogenous route, through the bowel, or through the peritoneum. In addition the hematogenous route practically opens all the organs of the body to the bacilli. This view is supported by Lubarsch,[8] who cites investigations on tuberculosis of the stomach (Simmonds, Bindo de Vecchi) of the heart muscle (de Vecchi), the muscles of the body (Saltykow), etc.

Of contributory interest is the work of Kelynack.[9] In 3,053 autopsies Kelynack found distinct hepatic cirrhosis in 121 instances. In 28 cases (23 per cent.) there existed a *tuberculous infection, either in the shape of active process, latent or old tuberculosis.* Pulmonary tuberculosis was found in 14 cases (12 males, 2 females). Among these cases the lungs and the peritoneum were simultaneously affected in 6 males and 1 female; the lungs alone in 5 males and 1 female; the peritoneum alone in 2 males and 2 females. Latent or old tuberculosis was present in 8 per cent. of the cases. The average age in active tuberculous processes was 45½ years; in tuberculous pulmonary disease, a little above 44 years; in disease of the peritoneum, barely 47 years; in latent or old pulmonary tubercles, a little over 44½ years.

Tuberculous pleuroperitonitis is discussed at length by Zelistratow.[10] Zelistratow gives a brief description of the clinical picture of the disease and five personal observations: One case was associated with general miliary tuberculosis; in another case the pulmonary and intestinal symptoms were so marked that the affection of the pleuræ and the peritoneum was of minor importance only. In Cases 3 and 4, the affection of the pleura and peritonitis were the only symptoms; in Case 5 these were the predominant symptoms.

The Influence of Proteids and Carbohydrates on Metabolism.—It was sought to determine the immediate effects of these two classes of foodstuffs on the products of metabolism. A. Gigon (*Skandin. Arch. f. Physiol.*, 1909, xxi, 351) made observations on himself, which were of ten hours' duration. Every quarter hour during the observations, doses of casein (155.6 gm.), dextrose (460 gm.) and of dextrose and casein (equal to the sum of these two) were administered. The experiments were carried out in the Sondén-Tigerstedt respiration apparatus, and in addition the exchange of nitrogen and phosphorus were determined. It was found that proteids as well as sugar increased the output of carbon dioxid and that the mixture of proteids and sugar increased the output of carbon dioxid to an extent which equaled the sum of the output from sugar and proteids when given separately. The doses of sugar, however, had no appreciable immediate effect on the exchange of nitrogen or phosphorus.

SURGICAL TREATMENT OF TUBERCULOUS PLEURISY, LUNG ABSCESS AND EMPYEMA *

EMIL G. BECK, M.D.
Surgeon to the North Chicago Hospital
CHICAGO

It is an established fact that at least 70 per cent. of all cases of the serofibrinous type of pleurisy in adults are of tuberculous origin, the figures of various observers varying from 15 per cent. to 82.6 per cent.

I need not here review the literature or quote statistics which establish this fact, since this has only recently been done by Lord[1] and in 1908 by S. Goodall,[2] but I shall briefly discuss the methods by which we may ascertain the true etiology of pleuritic effusions.

We shall here exclude the transudates due to circulatory disturbance, kidney affections, cancer, or injuries to the pleura and confine our study to the forms which are associated with or follow inflammatory diseases of the lungs, pleura or neighboring organs.

Dealing, then, with only inflammatory types of effusions, our first step is to determine what disease is its causative factor. Is it a tuberculous or one of the more acute forms of inflammation, such as lobar or bronchopneumonia, rheumatic arthritis, etc., or a suppurative disease of a neighboring organ, as, for instance, an abscess of the liver, spleen or mediastinum?

Since a large percentage of pleural effusions are associated with pulmonary tuberculosis, we shall naturally suspect most cases to be of such origin and shall search for verification.

METHODS OF DIAGNOSIS

The cytodiagnosis takes first place. It was first advanced by Widal and Ravaut, and verified by many observers, especially by Musgrave,[3] who analyzed seventy-two cases at the Massachusetts General Hospital. Musgrave approved Widal's formulated rules for differentiation, which are as follows:

1. A predominance of lymphocytes in the effusion indicates an early stage of tuberculosis of the lungs.
2. A predominance of polymorphonuclear leucocytes indicates that the effusion is due to an acute infectious process.
3. A large number of endothelial cells occurring in sheets or plaques means mechanical effusion or a transudate.

The tuberculous variety is divided into two classes: a class of cases which are forerunners of pulmonary tuberculosis, at least in which no tuberculous lesion can be discovered by physical examination, called the primary form, and then a group in which the pleurisy is associated with a well-pronounced tuberculous disease of the lung, the secondary form.

In the primary and most common form the lymphocytes predominate. During the first week or ten days in a tuberculous effusion the polynuclear cells may predominate, but these rapidly disappear and give place to a purely lymphocytic form.

---

* Read in the Section on Surgery of the American Medical Association, at the Sixtieth Annual Session, held at *Atlantic City*, June, 1909.

* Owing to lack of space the article is here slightly abbreviated. It appears in full in the Transactions of the Section and in the author's reprints.

3. Musgrave, P.: Examination of Pleural Fluids with Reference to their Etiology and Diagnostic Value, Boston Med. and Surg. Jour., 1904, pp. 317, 347, 377, 406.

In the secondary form, which is not so frequent (about 1 in 10) the sediment does not contain many lymphocytes, but consists principally of necrotic cells which are not entirely degenerated, the larger percentage being polynuclear.

Next to cytodiagnosis the process of "inoscopy"[4] is of diagnostic value. It enables us to find the tubercle bacilli in the effusion by means of a process of digestion of the fluid before staining.

The method of animal inoculations with the pleuritic fluid is another valuable aid in proving the correct diagnosis, but is, on account of the time required for the test, not very practical.

Another diagnostic aid which has recently become very popular is the tuberculin test, either by the cutaneous, subcutaneous, or conjunctival method. Its true value in this capacity is at the present time a subject of animated discussion in the medical world and will, no doubt, be decided by those who are now testing its reliability in thousands of cases.

The radiograph of the chest has, as yet, not received its merited appreciation as a diagnostic aid. By means of this quite recently developed adjunct we are able to recognize pleural effusion as well as pulmonary tuberculosis in the early stages in the lung, and when the two coexist we have evidence that the effusion is of tuberculous origin.

The literature on the radiograph as a diagnostic aid in diseases of the chest dates back as far as 1896 (Walsham[5]), and its more extensive application has been endorsed and perfected by Rieder,[6] Krause,[7] Holland[8] and many others.

The skiagraph is an accurate record of the presence and location of a lesion or fluid within the chest. Its interpretation is submitted to the acutest of our senses, the sense of sight. The eye, of all the senses, is the least liable to be deceived, and a perfect radiograph, if properly interpreted, is a valuable guide in the early diagnosis of tuberculosis, with or without effusion.

Recently I brought to the attention of the State Medical Society of Illinois an innovation in this diagnostic aid, which enables us not only to discern the earliest signs of tuberculous disease, but also to differentiate an active tuberculous process from a latent one, i. e., *the stereoradiograph of the chest* (Fig. 1). The stereoscopic effect brings into relief the structures of the lesions while the non-stereoscopic, single radiograph shows only a shadow. The active tuberculous process is recognized by dark shadows surrounded by a halo, the latter indicating the infiltrated area around the tuberculous focus.[9]

Quite different is the picture of an old healed tuberculous process, in which only scars remain in the lung tissue as relics of the disease. Here we find the shadows standing out clearly like spiders, surrounded by clear lung tissue.

Summing up our diagnostic aids, the clinical history, the physical findings, the chemical and bacteriological examination of the blood and secretions, the cytodiagnosis, inoscopy, the tuberculin test, animal inoculation and the stereoradiograph as guides in determining the character of pleuritic cases, we proceed to the treatment.

CURRENT METHODS OF TREATMENT

In the treatment there seem to be some inconsistencies. The idea that as soon as an effusion in the chest is discovered its immediate withdrawal is indicated is still too prevalent among practitioners and it is time that the medical profession take some definite position on this question.

In studying the literature of this subject one is impressed by the growing opinion of authorities that the pleural effusion in incipient cases of pulmonary tuberculosis is a factor promoting the cure of the disease. It is asserted that the collapse of the diseased lung produced by the effusion has a highly beneficial influence on the healing process. This, of course, has relation to the unilateral involvement alone, and many instances in which the spontaneous cure has taken place by either a pneumothorax or pleural effusion are reported in medical literature (Späth,[10] Konzelman[11]). The latter recently published twenty-five cases of all stages of pulmonary tuberculosis with intercurrent pleuritic effusion in which fourteen patients recovered and are able to work, and he regards the pleuritic effusion as the factor conducive to the healing of the underlying disease.

Lord, on the other hand, states that of every 10 cases of primary pleurisy 3 or 4 develop pulmonary or other tuberculosis within four to six years, and advises that every case of serofibrinous pleuritic effusion be treated as tuberculosis.

Autoserotherapy in serofibrinous pleurisy was first introduced by Gilbert and Fede,[12] and its efficiency in absorbing the pleuritic exudates has been corroborated by Nasetti[13] and by Schnutgen.[14] It consists in withdrawing by means of a Pravaz syringe 1 c.c. of the serofibrinous exudate and reinjecting the same at once subcutaneously. These injections are made daily for four or five days, according to the severity of the case, and within twelve to fifteen days the fluid in the chest cavity usually disappears. Bad after-effects were not noted. In fourteen out of fifteen cases of serofibrinous pleurisy thus treated by Schnutgen in the clinic of Professor Senator the results were positive.

Whether this form of treatment of removal of the exudate is of permanent value depends on these salient points: Does the disappearance of the fluid also cure the underlying disease, namely, the tuberculosis? Have these patients remained well or have they developed tuberculosis later on? Nasetti and Schnutgen have not made these points clear, except by suggesting that probably through the subcutaneous injection of the exudate a quantity of antitoxic and antibacterial substances gain entrance into the circulation.

Assuming, then, that the pleuritic effusion is conducive to the healing of tuberculous disease of the lung, is it not irrational to advocate its removal or favor its absorption by medical means, except when urgent symptoms, such as difficult breathing, extremely high blood pressure, or disturbance in the circulation, require immediate relief? Then, of course, it is advisable to withdraw a sufficient quantity to establish equilibrium.

The pleuritic effusion should not be regarded a disease. It is in reality a symptom, just as free fluid in the peritoneal cavity is a symptom of tuberculous salpingitis or tuberculous appendicitis. Its removal does not cure the underlying disease; on the contrary, it interferes with the healing process. The treatment of tuberculous pleurisy, therefore, should consist in the treatment of its causative factor, namely, the pulmonary tuberculosis.

Returning to the principle of compression of the lung in the treatment of unilateral tuberculosis, we may state that this was inaugurated by Forlanini[15] in 1894, and independently practiced by Murphy[16] by means of injections of nitrogen gas into the pleural cavity, where the adhesions of the lung did not prevent its introduction.

In Germany this method has been tried by Brauer,[17] who published his later experiences with the method in 1906, and recently Carl Lexer[18] published four cases so treated, and the results obtained by all these authors were quite encouraging.

Another method of lung compression was tried by A. Schmidt,[19] which consisted of the injection of oil instead of nitrogen gas.

More recently a radical method has been advised by Brauer, namely, the mobilization of the entire chest wall of the affected side by extrapleural resection of the entire length of as many ribs as will permit the remaining soft structures to fall against the diseased lung and prevent its expansion. It is essential to guard against injuring or opening the pleural space during the operation.

This work has been developed and extensively described by Professors Brauer[20] and Friedrich,[21] and, while the operative procedure is connected with danger and leaves the patient with deplorable deformity, they regard it as justifiable in cases in which the lives of those otherwise doomed unfortunates can be prolonged and made more comfortable.

Professor Friedrich reports ten cases treated in this manner, with three deaths and seven recoveries. This entire series consisted of patients with extensive unilateral pulmonary tuberculosis in which climatic and medical treatment had failed to prevent the spreading of the tuberculous process.

While these various methods differ in their application, the underlying principle in all of them is the same—namely, to bring about a collapse of the diseased lung, *thereby suspending its action and putting it to rest* for such length of time as may be required for the healing process.

To determine the causes which bring about this improvement has tempted many to investigation. Karl Spengler,[22] Baumler[23] and others have pointed out that pneumothorax could, in many cases of cavernous phthisis, produce a marked improvement, and the experiments of Forlanini, Murphy, Lemke,[24] in America, as well as Tuffier[25] in France and Brauer in Germany, with production of an artificial pneumothorax have shown that the compression of the diseased lung causes collapse of abscess cavities, arresting respiratory function and furthers cicatrization, and in consequence the lymphatic circulation is retarded and the absorption of toxic material from the diseased organ reduced. This effect is clinically evident in the cases thus treated, by a reduction of fever, cessation of cough and improvement in the general condition.

I am satisfied that this principle of immobilization of the lung is correct, and am certain that in working out some method which would facilitate its application without causing the great mortality or deformity of the present methods lies a promising field in the treatment of unilateral tuberculosis.

To exploit this valuable principle of lung collapse, and to perfect its means of application, has been my aim, but my experiments in this particular field are too recent and incomplete to permit their publication, although they seem very encouraging.

TREATMENT BY INJECTIONS OF VASELIN PASTE

At this point I desire to discuss the treatment of empyema and lung abscess, which, in a measure, led to my experiments in the treatment of tuberculous pleurisy.

During the past two years my brother, Dr. Carl Beck, and I have had considerable experience in the treatment of empyema by means of injections into the cavities of a liquefied paste made of 33 per cent. bismuth subnitrate and 67 per cent. of vaselin.[26]

The subject has, in connection with the treatment of chronic sinuses and suppurative conditions of the nasal accessory sinuses,[27] aroused considerable interest in the medical profession, since its simplicity and efficiency seem to have rendered it a valuable addition to our present methods of treatment of this class of chronic suppurative diseases.

In this paper I shall omit a review of the literature on the treatment of empyema, knowing that the medical profession is familiar with the methods in vogue; I shall confine myself to the consideration of this one method of treatment, which I first introduced in 1907, and to its further development since that time.

In December, 1907, I instituted this form of treatment in the first case, an abstract of the history of which is here cited:

Case 1.—*Empyema.*—Patient, H. A., aged 19. Family and personal history free from tuberculosis. January, 1907, an attack of pleurisy with effusion, soon changed into *empyema.* March 20, 1907: Resection of two ribs, evacuation of pus, drainage. A daily discharge of 2 to 3 ounces of fetid, green pus persisted in spite of all treatment until Dec. 20, 1907, when the patient was brought to me for treatment.

Bismuth Treatment.—Drainage-tube was removed and 120 gm. of bismuth-vaselin paste were injected into the suppurating cavity in the patient's chest. Two days later the injection was repeated, most of the previously injected paste having escaped with the discharging pus.

Later History.—After four days the discharge became serous, lost its foul odor and greatly diminished in quantity. Injections were repeated daily for a few days, and on the twelfth day the sinus closed and has remained so to date; the patient has gained 30 pounds and is in perfect health. Skiagraphs had been taken at intervals of two months which demonstrated the gradual absorption of the bismuth paste and the slow expansion of the lung where the abscess had existed.

[27] Beck, J. C.: Bismuth Paste in the Treatment of Suppuration of the Ear, Nose and Throat, The Journal A. M. A., *Jan. 9, 1909,* lii, 117.

This surprising result led me, and others also, to the further application of this simple method of treating such complicated and usually unfavorable cases, and six months later I was able to include in my report to the Sixth International Congress on Tuberculosis[28] 19 cases in which empyema and lung abscesses were treated by this method; 14 of the patients were then apparently cured, 4 improved and still under treatment, and one not improved, having discontinued treatment.

The sources of this report were quite reliable, such competent surgeons as Mayo, Ochsner, McGuire, etc., contributing to same in addition to the cases treated by myself.

Since the publication of these cases reports from many surgeons throughout this country and from abroad have convinced me that the application of the bismuth paste in the treatment of empyema surpasses even the good results obtained in treating other suppurative conditions by the bismuth paste method.

Nemanoff,[29] for instance, reports 4 cases of empyema treated in Professor Kadjan's clinic, St. Petersburg, in which one injection of the bismuth paste in each case was sufficient to produce complete closure, whereas the same patients had been treated at the clinic for six months without success. Eighty grams of the paste was the maximum dose.

Dr. A. J. Ochsner,[30] Chicago, reported to the American Surgical Association June 4, 1909, 14 cases of empyema, in all of which operation had been previously performed and the sinus failed to close, although in two of them the Estlander operation had been performed. In all these cases he applied the bismuth paste, with the result that twelve cases had completely healed and two patients are still under treatment and very much improved.

My experience and that of Dr. Carl Beck disposed of 10 cases of empyema and three cases of lung abscesses.

How many of these cases were of tuberculous origin it is difficult to say. In two of them we could positively prove the tuberculous nature, having found the bacilli in the discharge, and also proved its existence by animal inoculation.

Cases 1 to 9 inclusive were treated according to the method described in my previous publication. In the last four cases, 10 to 13 inclusive, important modifications were made, which may lead to entirely new and valuable improvement in the surgical treatment of empyema and lung abscess.

I shall briefly cite the histories of these thirteen cases, since nearly each one brings out some points, knowledge of which will be of value in the future treatment of similar cases.

Cases 2 and 3 are cited in detail elsewhere,[28] and I shall not give detailed histories of them in this paper.

CASE 2.—*Tuberculous Empyema.*—Patient was a young lawyer. Repeated withdrawals of pleuritic fluid in 1906 were followed by empyema. The same year five ribs were resected but the cavity did not collapse and discharged 100 c.c. of green pus every day.

Bismuth Treatment.—In April, 1908, the cavity was injected with 720 grams of bismuth paste, which was allowed to remain six weeks. At first the patient gained in weight, but at the end of six weeks he developed symptoms of bismuth intoxication, starting with slight cyanosis, then blue borders on his gums, loss of weight one pound a day and desquamative nephritis. As soon as the cause of these symptoms were explained the cavity was immediately filled with 500 c.c. warm sterile olive oil, which formed an emulsion with the paste, and was easily withdrawn the next day by means of a suction pump.

Later History.—All symptoms of intoxication disappeared in one week and patient regained his weight at the same rate that he had lost it. The pus became seropurulent and continued to discharge in quantities of one to two ounces a day until December, 1908, when the sinus closed and remained so until March, 1909, when it reopened and a quantity of green pus escaped, which, on examination, was found to be sterile. The cavity was refilled with pure, sterile petrolatum. It closed the following day and has remained closed to date. The final result of this case is not as yet decided, although the patient considers himself perfectly well and has chosen the occupation of chauffeur.

CASE 3.—*Lung Abscess.*—The report of this case, which is similar to Case 2, is given in full in the Transactions of the Sixth International Congress on Tuberculosis.

Both Cases 2 and 3 proved to be of tuberculous origin and in both the bacteriologic studies of the secretions, as well as tests by animal inoculation, proved that within the first six weeks of treatment with bismuth

paste the tubercle bacilli, as well as other micro-organisms, gradually diminished and finally disappeared. Ten c.c. of the secretions injected into the peritoneum of a guinea-pig did not produce tuberculosis or septic infection, while previous to the bismuth treatment one drop of the pus of each of these cases injected into guinea-pigs produced a tuberculosis within four weeks.

Case 4.—*Empyema.*—Chas. L., aged 18, had the grip in March, 1908; two weeks later developed pleurisy with effusion. Temperature 105. Aspiration was not performed until four weeks later, when resection of a rib was done and 2,000 c.c. of pus evacuated and drainage established. For three and a half months the pus continued to discharge profusely. July 20 30 gm. of bismuth paste were injected, whereupon the secretion ceased within twenty-four hours and sinus closed five days later. Patient gradually regained his health and sinus has not reopened.

Case 5.—*Empyema.*—M. O., aged 48, electrician, in 1906 developed an empyema, which, after resection of two ribs and drainage, failed to close. A radical operation was performed sixteen months later by resection of three more ribs, but even this was in vain, and bismuth injections were tried by his physician, and as these also were ineffective, the latter referred the patient to me for treatment. I saw him first on Aug. 2, 1908, with a sinus beneath the right scapula leading into a large cavity from which a seropurulent discharge of a sour, fetid odor escaped, causing severe eczema around the mouth of the sinus. After ten injections of the bismuth paste at intervals of three days the condition was no better. I then tried an injection of the paste to which 2 per cent. formalin had been added. This caused severe pain and the condition seemed aggravated. Patient discontinued treatment and came under the care of another physician, who recently reported to me that another radical operation had since been performed with the object of producing lung collapse, but patient did not rally and died shortly after the operation.

Case 6.—*Empyema.*—Mary H., 8 years old, had at the age of 6, developed empyema which, after several months of expectant medical treatment, ruptured spontaneously in two regions on the anterior left chest wall, leaving three sinuses discharging green, thick pus. Child was very much emaciated when brought to me in May, 1908; fever varied from 101 to 102 daily. Patient coughed and had shortness in respiration (20 to 42). There was dulness on the entire left chest, radiograph showing distinctly that side filled with fluid. Instead of the usual resection of ribs and drainage, I injected 60 grams of the bismuth paste through one of the sinuses. Temperature and cough persisted in a milder form for a period of three weeks; thereafter all symptoms disappeared and all three sinuses closed. While I could ascertain the presence of fluid in the pleura three months later the child had, nevertheless, gained 20 pounds in weight and is at present in perfect health, the fluid having been in the meantime entirely absorbed.

Bacteriologic examination of pus, carried out systematically, proved that the pus discharge became sterile twenty days after first injection.

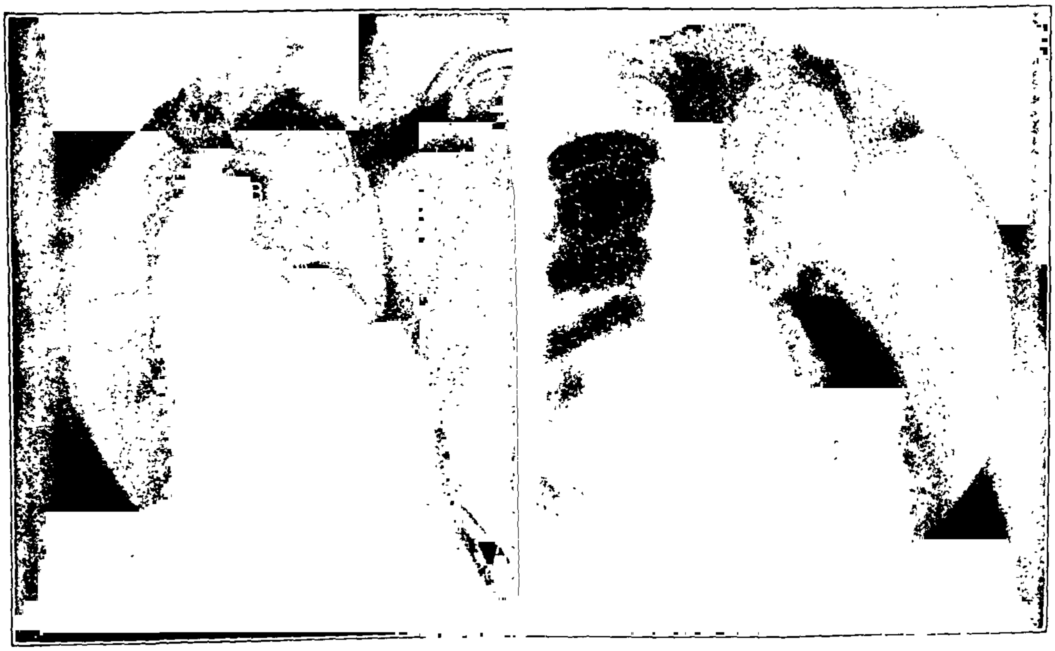
Case 7.—*Empyema.*—Miriam D., aged 5½ years, a delicate child, was taken sick at the age of 3 with acute lobar pneumonia. Empyema followed, and after the withdrawal of some of the fluid a resection of two ribs was performed by a surgeon in Ohio. In spite of perfect drainage and careful medical treatment the empyema continued discharging pus for one and one-half years, child failing gradually in health. As a last resort an Estlander operation was advised by the physician in charge, which the parents refused. In October, 1908, the child was brought to me for treatment. Her temperature varied from 99 to 101. Extreme emaciation and cough with pain as well as retraction of chest wall, were the principal symptoms. The small contracted opening into the chest secreted about 30 gm. of creamy pus daily. Through this sinus I injected 30 gm. of bismuth paste and took a radiograph, which showed that the cavity contained a large quantity of pus and the paste merely floated therein. Without resorting to further injections I observed the case for two weeks and noted a gradual decrease in the fever and cough, cessation of the discharge and closure of the sinus on tenth day. The child gained four pounds during the two weeks and the latest reports indicate that she has regained perfect health. (This patient was presented at the session of the American Medical Association, Atlantic City, June, 1909.)

The lesson learned from Cases 6 and 7 is the following:

1. It was not necessary to evacuate or drain off the pus from the pleural cavity before injecting the bismuth paste, and small quantities (30 to 60 gm.) were sufficient to produce the desired results.

2. Although the purulent exudate was not absorbed for several weeks after the bismuth injections had been

Fig. 2.—Stereoscopic view of sinus from empyema of twenty-eight years' standing, filled with bismuth paste (Case 9) closed in sixty days after first injection. A indicates rubber drain; B, arch of aorta.



made, its presence caused no elevation of temperature and sinuses closed in a comparatively short time.

3. While the discharge retained its purulent character after the bismuth injections, it was nevertheless found to be sterile.

Through the courtesy of Dr. W. C. Kirchner, surgeon-in-charge of the St. Louis City Hospital, who placed at my disposal a number of patients for demonstration of the bismuth paste treatment of sinuses before the members of the St. Louis Surgical Society, I injected, among other cases, one of empyema which I desire to include in this series. Dr. Kirchner's history of the case follows:

CASE 8.—*Empyema.*—Boy, aged 8, entered City Hospital, March 19, 1909, with a tentative diagnosis of appendicitis. Pulse, 140; respiration, 44; temperature, 101.6. After a few days of observation diagnosis of bronchopneumonia with pneumothorax was made.

Bismuth Treatment.—Temperature became normal three days after operation; discharge diminished but was very offensive under daily dressing until April 25, when patient was taken to clinic and 120 gm. of 33 per cent. bismuth paste, Formula 1, were injected into the pleura by Dr. E. Beck of Chicago. A second injection was given April 30 and on May 25 sinus was entirely closed and patient apparently cured.

Smear preparation of pus and the sputum were negative as to tubercle bacilli.

CASE 9.—*Empyema.*—G. T., aged 39, engineer, family history negative, had measles at the age of 15; no other disease. In 1881 he suffered from an attack of pneumonia, followed by accumulation of pus in the left pleura. Drainage was established by intercostal incision (Dr. Favill, Sr., Madison, Wis.) and rubber tubing inserted. The purulent discharge had persisted since 1881 and with only a few days intermission, a drainage tube had to be kept in the discharging sinus. Various methods, except radical operation, were tried in attempts to close the sinus, but all failed. In January, 1909, the patient was referred to me by Dr. H. B. Favill for treatment. His general health was very good, temperature and pulse normal, right lung normal, left lung and chest cavity very much retracted. Pus discharge of thick and of dark green color, contained staphylococci and a few streptococci.

Bismuth Treatment.—Injection of bismuth paste, Formula 1, 60 gm., filled out the entire contracted pleural sac. Temperature remained normal and discharge became serious on fifth day. Injections were repeated every third or fourth day, and after sixty days the sinus closed and patient returned to Arizona to resume his work.

This case is very instructive, since it teaches that even after twenty-eight years' constant suppuration an empyema may be obliterated by injection of the paste. The stereoradiograph (Fig. 2) of this case demonstrates distinctly in plastic effect the size and contour of the remaining pouch and likewise illustrates the efforts of Nature in her attempt to obliterate this cavity during the twenty-eight years. The ribs were so retracted that the intercostal spaces disappeared, the spinal column curved with its convexity to the well side, clavicle drawn down and diaphragm drawn up, all structures contracting toward one center, the old suppurating cavity.

The following case illustrates a new method of treatment of lung abscess, and for that reason I will give a more detailed history.

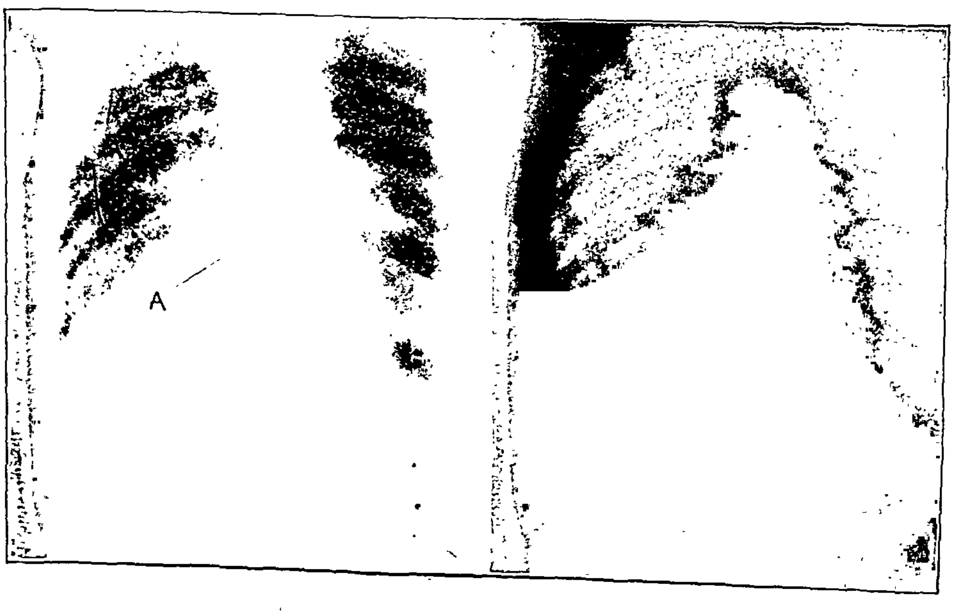
CASE 10.—*Abscess of Lung.*—Ellsworth D., aged 15, family history negative as to tuberculosis, was well until four years before examination, when he inhaled a brass pin-tack, the size of a lentil. Within a week he developed pneumonia. While the acute symptoms passed, he continued to expectorate pus and had a daily elevation of temperature from one-half to 3 degrees. In spite of all medical and climatic treatment, the above symptoms persisted for four years.

Examiantion.—I first saw him Dec. 15, 1908. His weight was 98 pounds, temperature 97, pulse 120, cyanotic and greatly distressed. The entire chest was resonant, except the right posterior and lower part, the dulness extending upward to the angle of the scapula. Stereoradiographs were taken (Fig. 3), which were of great assistance in the anatomic diagnosis, since they brought out, in plastic effect, the location of the abscess and its relation to the other structures, and show the foreign body. The expectoration had a fetid odor, was green in color, and at each coughing spell at least half an ounce of pus was expelled. The microscopic examination of the pus revealed the presence of streptococci, pneumococci and staphylococci. Cultures produced an abundant growth of streptococci.

An operation was decided on and a modified method of treating abscess of lung employed in this case as stated above.

Operation and Bismuth Treatment.—With the usual preliminary preparation for rib resection, the patient was chloroformed and under the guidance of the stereoradiograph an incision 10 cm. in length was made, directly over the region of the abscess, i. e., about 5 cm. below the angle of the scapula. Resection of 4 cm. each of seventh and eighth rib was made without opening the pleural cavity. Two catgut stitches were inserted by means of a curved needle, fastening the visceral pleura to the chest wall. Packing sterile gauze against the exposed parietal pleura, temporary sutures in the skin were inserted and the patient put to bed. On the third day another short chloroform anesthetic was given, the gauze packing removed, an incision of one inch made in the pleura, and, with the index finger the lung tissue was bored through until the

Fig. 3.—Stereoscopic view of lung abscess, treated by prophylactic bismuth paste method, closed in ten days. A' indicates abscess before operation



resistance indicated that the abscess wall had been reached. A pair of blunt, curved artery forceps were passed along the index-finger, pushed into the abscess and the cavity widely spread apart. About 100 gm. of a very offensive pus escaped. The hemorrhage was very slight. Five strips of gauze 2 inches in width were packed into the cavity, the ends of same being tied on the outside with a silk ligature. Patient's temperature, cyanosis and cough still continued. The following day the five strips of gauze were removed and the cavity injected with 100 gm. of 33 per cent. bismuth-vaselin paste. This produced a coughing spell, the patient expectorating a great deal of pus, mixed with the paste. No drainage-tube was inserted into the pleural opening. The injections were repeated daily for one week, and each time the patient emptied the contents of the abscess by coughing out some pus mixed with the yellow paste. At the end of ten days the external wound was entirely closed, symptoms of cough, fever and cyanosis disappeared.

Later History.—Four days after operation patient was sufficiently well to permit of my presenting him before the North Side Branch of the Chicago Medical Society and later at the Milwaukee Medical Society. His general condition now is excellent, his weight having increased from 98 to 124 pounds, and temperature has remained normal since one week subsequent to the operation.

It is not advisable to inject the paste while the patient is under anesthetic, since the pus may be drawn into the trachea and cause aspiration into the other lung.

While I have had opportunity to carry out this method of treating lung abscess in this one case only, the result is so striking and theoretically so plausible that I do not hesitate to recommend this procedure, in suitable cases, to anyone who is familiar with surgery of the chest.

Case 11.—*Empyema.*—Harold B., aged 8. Family history negative. Measles at 2 years of age. March 28, 1909, present illness began with high fever; diagnosis, lobar pneumonia. Patient not recovering as expected, physician brought him to the hospital April 9.

Physical examination revealed dulness over the entire right chest; left normal; radiograph (Fig. 4) corroborated physical findings. Temperature 100, pulse 120, respiration 32, marked cyanosis and emaciation were the cardinal symptoms.

Operation and Bismuth Treatment.—Operation April 11 by Dr. Carl Beck, consisting of the resection of one inch of the seventh rib. Rubber drain inserted after 350 c.c. of pus escaped. Pus continued to discharge and on the fourth day the rubber drain was removed and 100 grams of a 5 per cent. bismuth-vaselin paste (bismuth subnitrate 5 per cent., vaselin 95 per cent.) were injected into the cavity and a plain sterile gauze dressing applied. On the following day temperature became normal and all previous symptoms were ameliorated. Injection was repeated and six days later the secretion ceased. Sinus closed on the eleventh day after operation and has remained so to date.

Bacteriologic findings before bismuth injection had, as usual, been made, the smear preparation showing an abundance of staphylococci, and, in the culture media, a growth of staphylococci and Friedlander bacillus. Following the first injection a slow growth could be produced. After the second injection we could not produce any growth at all.

Case 12.—*Empyema.*—M., 2 years old, had a severe attack of pneumonia April 16, 1909, starting with a temperature of 105.8, pulse 136, respiration 48, which, after ten days developed into an empyema of the entire left chest. Resection of one rib by Dr. Carl Beck with introduction of drainage-tube produced only moderate relief. Temperature still ranged from 100 to 102 and respiration from 38 to 48 during the entire week following the operation.

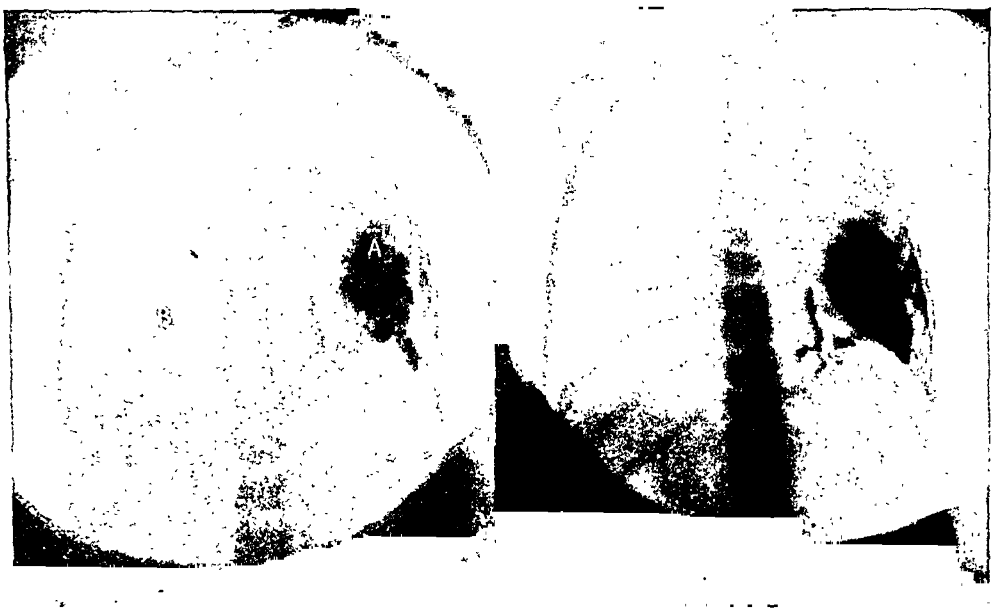
Bismuth Treatment.—On the eighth day after operation (May 3, 1909), an injection of 120 c.c. of a 5 per cent. bismuth-vaselin paste was made, and two days later the same quantity reinjected. Temperature fell to 99.4 (rectal), respiration to 30 within four days, and subsequently became normal, respiration 30. The pus became sterile after the first bismuth injection, but staphylococci reappeared a week later, and for this reason the opening has not been allowed to close. The injections will be continued until the secretion becomes sterile and then the closure of sinus permitted.

The general condition has markedly improved, cough disappeared, no signs of bismuth absorption present.

In the treatment of Cases 11 and 12 we deviated from the usual procedure in such cases in that the drainage tube was removed as early as the fourth day after operation and the cavities filled with a 5 per cent. bismuth paste instead of waiting several weeks for Nature to close it.

While the clinical results in these two cases are satisfactory and that complications need not be anticipated, nevertheless I do not, as yet, advocate this method as a routine procedure until a larger series of cases has proven its advantage over the present methods.

Fig. 4.—Stereoscopic view of empyema filled with bismuth paste four days after operation; healed in two weeks. A indicates 5 per cent. bismuth paste; B, heart dulness.



At any rate, anyone wishing to try this innovation should do so under careful guidance of daily microscopic examination of the secreted pus, and as long as the pus contains micro-organisms the opening should not be allowed to close.

Case 13.—*Empyema.*—G. E., aged 26, with negative history of tuberculosis, was attacked with a severe type of pneumonia March, 1909. Severe cough, high temperature, lasted for ten days, and instead of usual crisis the patient continued to have fever, from 100 to 103 daily.

Shortness of breath increased and he lost considerably in weight. In this condition, with a temperature of 103, rapid pulse and labored breathing, he came to the city May 15, 1909, and applied to Dr. Wynekoop for treatment, who called me in consultation. Diagnosis of empyema, based on all typical symptoms, was soon reached, and, moreover, corroborated by a stereoradiograph and thoracentesis, whereon an operation was proposed.

Operation and Bismuth Treatment.—On my suggestion the following procedure was employed in this case: May 16, 1909, under anesthetic, a resection of one rib was made and two quarts of thick, greenish, yellow pus were evacuated. Instead of inserting a rubber tube, a quantity of 250 c.c. of 5 per cent. bismuth vaselin paste was at once injected and a plain sterile gauze dressing placed against the incision.

Later History.—Temperature, pulse and respiration became normal within twenty-four hours after operation and remained so to date (May 27). Patient is gaining in weight and strength, eats with great relish and has no difficulty in breathing. The purulent secretion changed into a seropurulent within twenty-four hours, and at the end of the first week only a small quantity of sterile serous discharge escaped into the dressing. At present (two weeks after operation) only a little vaselin escapes from the contracted small opening.

The procedure employed in this case would certainly be an ideal method if we were certain to obtain in every case the same favorable result. One case, however, no matter how brilliant the result may be, is not conclusive, and here, as in Cases 11 and 12, we must produce a large series of similar results before we can safely advocate this procedure as a routine method in treating empyema.

In reviewing the histories of these thirteen cases one can follow the step-like development and the gradual approach to what we aim to make a satisfactory method of treating empyema; a method which would do away with the rubber drain, the everlasting daily dressing, the continued suppuration which causes the pleura to become so much thickened that the expansion of the lung is practically impossible; a method which would cast into eternal oblivion the necessity for such radical, deforming and dangerous operation as the resection of the chest wall.

The factors contributing to the efficacy of this method of treatment of chronic suppurative diseases have been studied by me and published in the "Transactions of the Sixth International Congress on Tuberculosis" and my conclusions since that time have not changed materially.

Further investigations in the pathology and reparative processes are being carried on by my brother, Dr. Carl Beck, and will be published in due time.

CAUSES EFFECTING HEALING PROCESS

1. Bismuth-vaselin paste (proportion one part bismuth and two parts vaselin), when injected into suppurative cavities or sinuses, produces chemotaxis. In other words, it attracts the leucocytes to the parts injected, where the phagocytic action destroys the bacteria present in the walls and channels of the sinuses. A systematic examination of the secretions by smear and preparation, cultures, and frequently by animal inoculation before and after the injections of the paste, have proved to me the bactericidal action of the bismuth subnitrate when brought in contact with living tissues. Tubercle bacilli are no exception, this fact having been discovered in Case 2 and corroborated in Case 3. They are rarely found in the pus from tuberculous sinuses; more often, however, in tuberculous empyema. They lodge in the granulations and walls of abscess cavities. The bismuth paste, coming in contact with the walls containing the bacilli, induces chemotaxis, and the leucocytes thus drawn to the injected region destroy the micro-organisms present. This, to a certain degree, explains the interesting microscopic findings of the morphologic changes and destruction of the bacilli.

2. The chemical action of the bismuth subnitrate in the destruction of the micro-organisms seems to be very slight, as shown by experiments on cultures *in vitro*.

3. Distention of the abscess cavities with the paste and pressure can play only a subordinate part in the therapeutic effect. In some of these empyemas (Cases 6 and 7) only a small quantity was injected into a large cavity containing quantities of pus, and the results were all that could be desired.

4. The exposure of the injected parts to the *x*-ray can, likewise, play only a secondary part in the healing process, as I have received reports from many surgeons who obtained satisfactory results without the use of the *x*-ray. I believe, however, that in tuberculous sinuses from joint disease the application of the *x*-ray often accelerates the healing.

TECHNIC IN CHEST CASES

The technic of bismuth injections employed in abscess cavities in the chest differs somewhat from the one applied in sinuses. In the chest we have to deal with an infected cavity which has a rigid chest wall on one side, and the retracted, but more or less resilient, lung on the other. It is generally believed that if the air could be prevented from rushing into the cavity with each inspiration the lung would expand and fill up the space, but this does not explain why in many cases the abscesses do not heal when this principle is carried out by the suction-pump of Perthes,[31] and in recent tuberculous cases it is not even desirable.

After a radiograph of the cavity has been taken and an examination of the secretion has been made, it is injected with 100 gm. of bismuth paste, Formula 1. Gauze dressings are applied daily until sinus closes. Should temperature rise above 101 F., or the patient complain of severe pressure, the accumulated fluid should be drained off and the opening again allowed to close. If the temperature remains normal and no unpleasant symptoms arise the 100 gm. of paste injected may be left in for absorption, provided no signs of bismuth intoxication arise. Repetition of the injection is necessary only when the bismuth paste has discharged with the pus, and micro-organisms are still found in the secretions. In my early experience I supposed that the cavity had to be overdistended with the paste in order to produce healing, and I introduced as much as the cavity would hold. Such large quantities are not only unnecessary but are also liable to produce bismuth intoxication. Should any signs of this poisoning appear the bismuth must at once be dissolved by warm olive-oil and withdrawn by suction-pump.

It is noteworthy that the tuberculous empyema is far more resistant to any form of treatment than that of pneumococcus or other varieties. Murphy states that a very large percentage of empyema in adults is of the tuberculous form and that these rarely undergo absorption or break into a bronchus.

From personal communication with Dr. Moore, medical superintendent of the Dunning Hospital for Consumptives, an institution which takes care of an average of 400 patients in the progressive stages, I have the information that in the past four years he observed, in 5,000 cases treated, 25 cases of tuberculous empyema, and, whether operated on or not, all of the patients succumbed to the original disease.

---

[31] Perthes: Mitt. a. d. Grenzgeb. d. Med. u. Chir., vii, Heft 4, 5.

These tuberculous empyemas are usually preceded by the serofibrinous pleurisy, which, either by frequent tapping or spontaneously, become secondarily infected. Operation is usually resorted to and, as a rule, the subsequent treatment is very tedious and unsatisfactory.

In my series of cases two were proved to be of tuberculous variety, and, while I do not consider the patients perfectly cured, they have so much improved as to permit the resumption of their pursuits in life, one of them having conducted his own campaign for state's attorney and won in the battle, the other taking a position as chauffeur.

Empyemas in children, or those following acute inflammatory condition in adults, give a very much brighter outlook for recovery. In children the drainage is usually rapidly followed by expansion of the lung and spontaneous closure of the sinus, and the majority of cases of the non-tuberculous type in adults will yield to the accepted methods of surgical treatment. A small percentage of cases, however, even of these types, will resist all medical and surgical treatment, and the sinuses keep on discharging pus indefinitely.

The failures are thus explained:

1. As long as the walls lining the pleural cavity are the seat of living micro-organisms, especially tubercle bacilli, an obliteration of the space can not be expected.
2. After suppuration has existed for years and the pleura has become very thick and the lung cicatrized, the expansion of the lung will not be possible.

The requirements therefore are:

A cavity free from micro-organisms and the lung still sufficiently resilient for expansion.

The method here described and employed in the cases enumerated, I believe, possesses to a marked degree the means essential to obliteration of abscess cavities. The introduction of bismuth paste has, as a rule, produced, by a process of local leucocytosis, a sterilization of the secretion, and in most cases softened the indurated pleura sufficiently to allow moderate expansion of the lung and obliteration of the space.

I realize that a series of thirteen cases is too small and the time since the application of this new method too short to admit of formulating fast rules. My aim in thus prematurely bringing the subject before the profession, is to stimulate others to help in working out an ideal method of treating lung abscesses and empyema.

92 State Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. POWERS, BECK, FRIEDRICH, MEYER, AND GREEN AND JANEWAY—A SYMPOSIUM ON THORACIC SURGERY *

Dr. DeForest Willard, Philadelphia: We all know the difficulties of thoracic surgery. We have invaded the abdomen and cranial cavity with comparative impunity and safety. Why? Because the cranial and abdominal cavities contain organs which are not essential to immediate life; but in the thorax are located the lungs and heart, without which no person can live more than a few moments, while the abdominal organs can be incapacitated for work for a long period of time. Therefore, we have approached this region with fear and trepidation. Since the invention of cabinets for positive and negative pressure, and for producing differential pressure, the thorax has become a more hopeful field for the surgeon, and we may yet hope in due time to meet the difficulties now before us with better preparation than heretofore, especially in cases of sudden pneumothorax, which have always been a *bête noir* in surgery. To treat a diseased lung is not so difficult, because it is crippled already, and it is not nearly so dangerous as is an acute pneumothorax. For many years I have been much interested in chest surgery. It has been my hope that we might be able to treat a tuberculous cavity in the lung by opening and drainage. The experiments I performed twenty years ago on dogs and experience since that time on human beings, has convinced me that if there were a single apex cavity it would be a feasible and successful operation, but, unfortunately, in tuberculosis of the lung, there is not, as a rule, a single cavity, but many cavities scattered throughout the lung, and while we could open and drain one, others would remain. In the experiments I performed many years ago, I found great difficulty in preventing leakage from the bronchial tube into the pleural cavity. If I closed the external opening through the walls, speedy death would be the result from this constant leakage of air. The method described by Meyer of crushing the bronchus will certainly be an advantage in preventing such an accident, especially when the bronchus is ligated and sutured afterward. In extirpation and pneumectomy, I am sure that the methods he described will be perfectly possible by means of differential pressure. The size of the opening in the chest wall is also a factor in determining the occurrence of pneumothorax. If we can establish tolerance by means of partial closure, we have gained much. In regard to mediastinal work, the transverse opening employed by Friedrich is by far the most advantageous, and is much better than the vertical incision. Judging from the benefits I have derived in surgery from the use of bismuth paste, in empyema, I feel satisfied that its influence on the diseased pleura will be useful. I am much pleased with Dr. Meyer's aëronautic invention, and we may hope that by means of this and the aëroplane, surgeons will in the future be able to take their patients up into the air a few thousand feet and operate, free from the dirt and dust of the street.

Dr. S. J. Meltzer, New York: The statement frequently made by the followers of the Brauer method, that there is no functional difference between this method and that of Sauerbruch, physiologically, is incorrect. While under the Sauerbruch method the expiration does not differ from that which takes place under normal conditions, the expiration under the Brauer method, that is, the removal of the carbon dioxid, has to take place against the atmospheric pressure plus a pressure of 8 or 10 millimeters of mercury. That is the reason why in operations under overpressure the blood often looks dark.

The slowing of the heart which occurs under distention of the lungs leads to actual stoppage of the heart. This is either a reflex act or is due to a stimulation of the vagus centers in the medulla, by the carbon dioxid. At any rate, it is important to know that the grave situation can be easily relieved by an intravenous injection of atropin. I wish also to refer briefly to a physiologic observation we made in the laboratory at the Rockefeller Institute which promises, we believe, to be of considerable practical importance. We found that under a certain method of insufflation of air, the animal does not require any respiratory movements of its own to maintain its life. In under-pressure or over-pressure, the methods are employed, it is assumed, only to prevent the collapse of the lungs while the respiration is carried on by the animal itself. This assumption, we found, is well founded. If curare is given to an animal breathing under the Brauer method, the animal dies in a few minutes. By our method the animal may be completely curarised and will continue to live for many hours. The method consists in introducing a tube into the trachea as far down as the bifurcation and conducting a continuous stream of air under a pressure of from 10 to 15 millimeters of mercury through this tube. The removal of the air carrying the carbon dioxid takes place through the space between the tube and tracheal wall driven by this pressure instead of against it.

Dr. G. E. Fell, *Buffalo, N. Y.*: It is natural from the work I did a score of years past that I should be greatly interested in this subject. My apparatus with which I have resuscitated many human beings, who have stopped breathing, is exceedingly simple after it has been studied. With it one may keep up respiration by rhythmically pressing on the piston of the air-valve, making the intervals as long or as short as is desired. In the final closure of the chest cavity, the entire pleural space of the thorax is filled with the lungs by pressing down, the piston keeping up a continuous inflation within reason, holding it as long as desired; the chest cavity is closed air tight, and autorespiration should ensue, all other matters being satisfactory. I believe that positive pressure is the best when properly applied. It is unquestionably too valuable to be pushed aside, and will be utilized on account of its portability much more than the cabinet method. In thoracic surgery, it will permit absolute control of the lung movements, or of inspiration or expiration, the latter being really passive. This was practically proved by the work I did in 1887-1888, and the following decade, the real discovery of practical forced, instrumental respiration on man. The method of using the anesthetic and oxygen with this apparatus is practical and the quantity can be gauged to a nicety. No other apparatus I have heard of compares with it in this respect, and in every other application it has proved its actual value as a means of respiring for human beings. If, as has been done in my experience, we can breathe for a human being for three or four days and nights, and save life, we should be enabled to keep up respiration for surgical purposes at the most when only an hour or so would be required. My demonstrations of its value have been varied, and it has been described here and there in my writings, although then it was not so complete as now. Notwithstanding this, it has not been fully understood by those who have discredited it.

---

* The papers of Drs. Friedrich, Meyer, and Janeway and Green appeared in The Journal last week.

DR. SAMUEL ROBINSON, Boston: At the end of two and a half years of experimental surgery, it has been my good fortune within the last three months to visit Marburg, Germany, and I would express my thanks to Professor Friedrich for his courtesy in allowing me to work with Professor Sauerbruch in his clinic. During the last three years I have performed animal operations under positive and negative pressure. I have operated on human beings with positive pressure and have witnessed operations on human beings under negative pressure. I think that I have seen most of the apparatus in this country and in Germany, which are indeed many. The question in the minds of many surgeons to-day is: "Shall I employ pressure difference in my operations on the thorax or not?" Nothing would be more contributory to the solution of the problem than to have a number of surgeons operate on all individuals who present themselves with thoracic disturbances without pressure difference. If any man is convinced that pressure difference is unnecessary and will operate on every one with the same courage with which surgeons are now operating under pressure difference, his results will be the greatest contribution to this branch of surgery. Knowing the accidents that may happen, I personally am not ready to take such risks. To those who have concluded that pressure difference should at least be available in thoracic operations, the question that arises is: Is positive or negative pressure to be preferred? I urge you not to lose unnecessary time in this choice of methods. German physiologists have shown that the negative pressure method is the better imitation of the normal respiration. On the other hand, it has been proved that the results under positive and negative pressure of like value, and the choice of apparatus depends on which is best adapted for your facilities. Many apparatus are portable and best adapted for certain surgeons; other more cumbersome ones are best for hospital use. Our indebtedness to Dr. Meyer for the cabinet which he has constructed has not, I think, been sufficiently emphasized, for although he cannot expect us all to have an apparatus which combines the two methods, he has nevertheless an opportunity to determine whether or not one or the other method is applicable to a certain class of thoracic cases. Kuttner has operated alternately with both methods, but having started an operation with one he cannot change to the other, a possibility which is beautifully carried out in Dr. Meyer's apparatus. A word about empyema. It is safe to say that for the present we shall not all adopt the methods of Dr. Beck or Dr. Murphy, although their results are promising and may eventually become the methods of choice. Until that time arrives, I would emphasize the fact that most of the cases suitable for bismuth injection or thoracoplastic operation result from the neglect of the surgeon who has operated in the first stage, and I urge surgeons to see to it that the lung is brought to the chest wall in the after-treatment of empyema or in accidental pleural injuries. If this is accomplished, this discussion of the proper method of treating old empyema sinuses will no longer be a question for us to consider.

DR. N. W. GREEN, New York: Dr. Meyer's paper was especially interesting, where he showed the method of resection of the lung and of dealing with the bronchi. Of course, the closure of the bronchus is the important step in resecting the lung, and Dr. Meyer combats infection from this source, by his angiotribe method. We also have used a similar method, cutting the bronchus with the cautery after pinching it and ligating the four blood-vessels at the hilus of the lung over it. The entire lung can be taken out with ease. We must realize that there is a large field for operative work in the chest, when we consider that the pathologic conditions in the chest are so numerous, and that tuberculous processes in the lung lie dormant for many years. Dr. Willard mentioned that the cavities in the lung may be numerous or multiple. In the ordinary thoracotomy under differential pressure we can open the chest with impunity; we can explore the lung surface, and, in many cases, we can tell whether there is only one diseased spot or many, and be prepared to apply the correct treatment without causing any injury. Dr. Meltzer mentioned the use of atropin. Last year Dr. Schäfer of Edinburgh, Scotland, referred to its use in prevention of shock, and we have found it useful for that purpose in our operative work. A small dose of atropin, from 1/100 to 1/50 of a grain, may be administered a few minutes before beginning the anesthesia. Dr. Fell spoke of over-expansion of the lung. There is not so much danger of this in his work. One can raise the pressure to 60 millimeters while the chest wall is intact, without causing rupture of the lung, but it is a different matter when the lung is outside of the chest cavity. In that case we may do injury. I wish to commend to you the idea of thoracotomy under differential pressure for exploration, either for esophagus involvement or for pulmonary involvement of one form or another. I think that the procedure will probably come into more universal use even as exploratory operations are performed for abdominal disease, after all other means of diagnosis have been employed.

DR. J. B. MURPHY, Chicago: In empyema that does not communicate with a bronchus and that does not communicate by an external sinus with the body surface, what shall we do? Render that cavity sterile without opening it, and permit absorption of the sterile fluid to take place. This can be accomplished first, by simple aspiration and its change in the circulation in the wall of the abscess; second, by the injection into the abscess of some enzyme or irritant that causes polymorphonuclear leucocytosis in the cavity. Pleuritic effusions are not absorbed like many of the acute pus accumulations in other parts of the body that have ceased to destroy, because they have in them no material that converts the albuminoid into absorbable peptones. We can overcome that by injection of sterile trypsin, or better and more easily, by injecting into the pleural cavity a few drams or ounces of a 2 per cent. solution of formalin in glycerin. Eleven years ago, at Denver, I discussed the treatment of pleurisy with effusion in tuberculosis. Professor Friedrich has given us an operation which will enable us to accomplish exactly what Nature does, namely, pulmonary compression for repair of the tuberculous lesion, which we have heretofore tried to prevent by early aspiration of the fluid. He has shown that by excising a portion of the chest wall the lung is permitted to contract or to be compressed during the process of repair; a procedure which is in accordance with our knowledge of the repair of tuberculosis in any part of the body. I showed at the Denver Session that the fluid effusion compresses the lung and favors the processes of repair, and that the nitrogen or air could be used as a substitute for the fluid. When the tuberculous focus is about to penetrate the surface of the lung through the pleura, Nature produces in the pleura an effusion, and that effusion gradually compresses that lung up to one corner and holds it there while the process of repair is going on, and finally removes this by absorption. That effusion is of advantage during the process of repair if the effusion is sterile. When it becomes an empyema, when it becomes septic, then we have in addition the destructive effects of the infection; we have increased temperature and sepsis, which is very detrimental to the patient's general condition and to the process of repair; therefore it must be rendered sterile by aspiration and repeated injections of formalin solution until pus ceases to form. To other operations for removal of lung many years ago, I added experiments to show how the bronchus could be closed, and how a portion of the lung could be excised successfully. This last can be accomplished when a whole lobe is to be removed by dislocating it to the surface and allowing it to adhere and slough off. Furthermore, drainage of a circumscribed cavity of a tuberculous lung by external drainage has to be taken into account in another element—the repair of the tuberculous process after it has been drained is always slow and frequently fails of completion. If I were to lay down a law in the management of empyema, it would be this: No case of pus in the pleural cavity, not connecting with a bronchus, should ever be opened or drained until the surgeon has figured out how he is going to close or obliterate that cavity. It is easy to open the chest wall in empyema, and often impossible to close it.

Dr. Beck has brought into this field, as it appears now, a most valuable aid in the closure of these sinuses. I regret that I have not had any experience in this method. The element of pneumothorax in connection with the surgery of the lung, *per se*, is a very minor one, and positive or negative pressure apparatus will have little value in the surgery of the lung and pleura. It will have a place in the surgery of the esophagus, and in surgery where one has to remove a tumor from the mediastinum, as shown by Professor Friedrich, where one may perhaps open the pleura on both sides. Notwithstanding the air admission on one side, if the mediastinum be immobilized so that it does not vibrate during the operation, one lung can be completely compressed and the surgeon can work with that lung compressed or drawn out of the chest cavity without any inconvenience as respiratory exchange goes on in the other lung. With the mediastinum vibrating there is no respiratory exchange.

Dr. P. C. Hartford, East Palestine, Ohio: Knowing that an actual demonstration would be better than to read a paper, I have the pleasure of showing you a case of empyema cured by Dr. Beck's method of injecting bismuth paste. The little girl was operated on four years ago for empyema. The first operation proved a failure, a sinus remaining. The second operation, performed two years later, was also a failure. I saw the little girl for the first time last October, when she had a large sinus in her side. The first operation was a partial resection of the rib, with drainage four months after the pneumonia had occurred. The second operation was done to heal the old sinus. One injection of the bismuth paste entirely healed the cavity. The little girl has had no rise of temperature and no difficulty whatever since the first injection.

Dr. A. J. Ochsner, Chicago: I consider the use of bismuth paste in the treatment of sinuses and abscesses following operations for empyema as one of the most valuable contributions to surgery during the past five or ten years. In empyema and abscess following empyema, I have not used it as a prophylactic, as suggested by Dr. Beck, but I have used it in patients who had been operated on before this method was introduced, sinuses that had remained open for months or even years; patients who had been operated on by resection of the ribs primarily, and secondarily by Estlander's operation, and in one case I performed a Schede operation after these two operations. Of fourteen patients whom I have treated by this method, and I have two under treatment now, in twelve the sinuses have healed; and I am sure that they would have remained unhealed up to the present time were it not for this method. One feature of the method is that it does not matter whether the bronchus opens into the cavity or not. All physicians know how difficult it was formerly to treat and heal these cases, but with this method it does not matter how extensive the cavity is. I have had several cases in which I have been able to inject 600 or 700 c.c. of bismuth paste, and still the sinuses have healed. Therefore, I wish to impress on you the wisdom of using this bismuth paste in cases of empyema, no matter how bad they are. You will find that in a week or ten days or, perhaps, two weeks, the rise of temperature will disappear, and these patients that go about in a septic condition will no longer be septic. The anemia will begin to disappear, and you will be astonished to note the progress that these patients make.

A word as to the method of application. In speaking with various surgeons, I was impressed with the fact that they imagined that it was a difficult or troublesome problem to treat patients in this way. I take a large glass syringe, put the point or nozzle into the abscess, or if there is a sinus, put a rubber tube into the abscess through the sinus. I heat one part of bismuth and two parts of vaselin to 110 or 120 F., pour the mixture into the cavity until it is full and put a stopper of gauze into the outer opening. If the patient shows irritation, or bismuth poisoning, I put a rubber tube into the cavity, pour in hot olive oil, let the bismuth run out, and the symptoms of poisoning disappear, although in my own cases I have not had to do this. In 2 cases I have encountered in the practice of other surgeons, this procedure had to be carried out.

Dr. Charles A. Powers, Denver: I am impressed by the probable value of this operation of major thoracoplasty in pulmonary tuberculosis which has been brought to us by Professor Friedrich. It is employed by him in practically hopeless cases, and a number of his patients have shown marked improvement. I had the pleasure of witnessing one of these operations in Marburg in 1908, and was impressed by the skill, rapidity and thoroughness with which Professor Friedrich removed all the ribs from the first to the tenth, inclusive, in a young man with a progressive, unilateral cavernous pulmonary tuberculosis. The operation at first thought seems a staggering one, but I believe that there may be much of value in it. The modified pneumatic cabinet of Dr. Willy Meyer marks a definite advance in pulmonary surgery.

Dr. E. G. Beck, Chicago: The point to which I wish to speak now is again to call attention to the fact that there is danger of bismuth poisoning in this method. I do not think that it is necessary to use such large quantities of the paste. In Dr. Hartford's case only 1 ounce was used and the result was a good one. Furthermore, in case there is a blue line on the gums, this does not mean that it is a case of poisoning. I regard that as a favorable sign, because at that time the patients improve most rapidly. If, however, you find ulceration of the gums or pharynx or albumin in the urine, excessive loss of weight or cyanosis, then it is time to remove the paste, but not by scraping. If the cavity be scraped greater absorption is invited and more poisoning. This mistake was made in one case of which I have knowledge, and the patient died. One way to prevent the occurrence of poisoning is to inject warm olive oil into the cavity, leave it there for twenty-four hours, when it will have formed a gray emulsion which can easily be sucked out by a syringe, and the patient will begin to improve from that moment.

Professor Friedrich, Marburg, Germany: The important thing to be learned from this discussion is that we are in a position to treat empyema successfully, as shown by Murphy, Ochsner and Beck. We are getting beyond the point where empyema must be treated by resection of the ribs. Time forbids answering Dr. Powers' question *in extenso*. As to the use of positive and negative pressure, I think we must say that in most intrathoracic procedures these things are unnecessary; on the other hand, some of the successes in lung surgery depend on these measures. We have not advanced so far in lung surgery as we have in abdominal surgery. We do not hesitate to perform an exploratory laparotomy, and it is extremely probable that before long we will do likewise in the case of lung tumors, and it is here that the differential pressure method will be of great usefulness. We can expose the lung, inspect it, palpate it without doing injury, and when we can guarantee that we can employ asepsis as in exploratory laparotomy, greater progress will be insured than I have dared to indicate in my paper. I wish to say that in America I have had an unusual opportunity to see the unexpected and unusual success of animal experimentation, which must be our object if we want to see lung surgery advance. We must resort to procedures that make lung intervention free from danger. If the pulmonary artery to one lobe of the lung is tied, there results a complete atrophy of that lobe without any evidence or manifestation of disease or pathologic change. Six weeks after the tying, which is a very easy procedure, the lobe has atrophied completely and is empty of blood. For the extirpation of a tumor, that knowledge is of the greatest importance.

DR. WILLY MEYER, New York: From what I have seen in operations on dogs and human beings, I fully agree with Professor Friedrich that "when it comes to opening the chest wall in cases in which the pleura and lungs are adherent, we can, of course, operate safely without differential pressure, but if there are no adhesions present, there can be no doubt that the safe operation is that done under differential pressure." If we want to make progress in this field, and we all want to do that, now that the thoracic cavity has been opened to surgery in a safe way, we must recognize the fundamental rule: Operate under differential pressure if there are no adhesions between pulmonal and costal pleura. The gravity of the occurrence of an acute pneumothorax is no bugbear. It makes a great difference whether we operate on a healthy dog or on a diseased human being. If we must operate on the diseased human being, and there are no adhesions present, we can do a safe exploratory thoracotomy under differential pressure; the patient will most probably stand the operation well, provided he stands the anesthesia. If we do the operation without differential pressure, there is a chance that the patient will die in direct consequence of the operation. Therefore, the discoveries of Sauerbruch and Brauer operating under negative or positive differential pressure, are fundamental principles in intrathoracic surgical work. With regard to the preliminary hypodermic use of atropin, I read recently the report of an experimenter, published in THE JOURNAL, Jan. 30, 1909, p. 328. Every fowl operated on by these colleagues had died. When atropin was first used, the animals recovered. I have seen in my work on dogs that a hypodermic of atropin reduces the seriousness of major operations. Cancer of the esophagus is the field in which the surgeon can truly help suffering humanity. So far, every patient with cancer of the esophagus must die. In making use of operating under differential pressure, every surgeon of dexterity should now help in solving this problem. We must succeed in saving some of these patients, and I am sure that we will succeed.

With reference to Dr. Willard's humorous remark that with an aëroplane and my cabinet we would soon hear of patients being lifted into the skies and operated on there, I would say that in using my new large chamber we can place the patient up in the clouds, while the surgeon remains on earth. Converting the positive pressure cabinet, which forms a part of the large negative chamber into a negative one by reversing the pump. We produced negative pressure instead of positive, in the small chamber and a still lower negative pressure in the large chamber. Thus, for instance, operated with 744 degrees mercury in the large chamber and 752 in the small one. We simply shifted the atmosphere downward. In other words, my new apparatus makes thoracic work independent with reference to having 760 degrees mercury always represent one factor of the differential pressure. Perhaps this independence may prove of importance in the future when operating on tuberculous lungs. Thus, what Dr. Willard prophesied might happen, has happened already: a surgeon in Philadelphia or New York can operate on a patient who is lifted up into the clouds of the Adirondack Mountains.

DR. H. H. JANEWAY, New York: While there can be no question that negative and positive pressure is of advantage, I want to emphasize the fact that intrathoracic operations can be done better when we use artificial respiration than when we do not. In operations on the esophagus, this is true to a still greater degree. The most complicated conditions are made easy, and successful issue is the rule. This is a definite surgical problem that presents itself, and we must not shrink from it. By systematic experiments on animals, and by carefully compiling our observations on human beings, there is no reason why we should not hope some day to find a successful solution of the problem. It certainly is not beyond our powers, but we must observe, study and learn.

THE CLINICAL ESTIMATION OF AMMONIA IN THE URINE BY THE FORMALIN METHOD *

E. W. BROWN, M.D.
Assistant Surgeon, U. S. Navy, on duty on the U. S. S. *Vermont*

The great importance of the routine estimation of the urinary ammonia in cases of acidosis is now attracting much attention, and the object of this paper is to report the study of a method the technic of which is so simple as to be available to the average clinical worker with limited laboratory facilities. It is hoped that the more general adoption of the ammonia determination will thus be encouraged. Of the several forms of acidosis always tending to develop symptoms of acid intoxication, those which may occur in diabetes and pregnancy are probably the most important. The chief urinary symptoms are: (1) the presence of the so-called acetone bodies, i. e., acetone, diacetic acid, and, in severe cases, beta-oxybutyric acid; (2) a marked increase in the relative and absolute output of ammonia. The quantitative determination of the acetone bodies, while highly desirable from the standpoints of both prognosis and treatment, is long and difficult. The ammonia, on the other hand, can be readily determined and affords an index not only as to the quantity of acetone bodies excreted, but to the total amount produced; in other words, it points out the degree of acidosis. The clinical determination of ammonia, therefore, is the only procedure readily practicable at present for indicating the danger-line of acid intoxication in diabetes and is of vastly greater significance than the sugar estimation. Emerson[1] says in this connection:

> Patients with much acidosis die of coma unless from some intercurrent disease, and there is no case of true coma yet studied without a previous acidosis. The amount of these (acid) bodies is perhaps better estimated by the ammonia output than by their direct determination, since the symptoms are caused by a withdrawal of the body alkali which the ammonia protects. An increase of ammonia means the presence of at least 10 gm. of oxybutyric acid per day, a marked increase of about 15 gm., 4 gm. of ammonia indicating 16 gm. of the acid. Naunyn considers that over 3 gm. of ammonia per day means danger of coma, and that if 4 gm. per day are excreted coma is sure to result unless alkaline treatment is begun at once.

On an ordinary mixed diet the absolute daily ammonia output is normally about 0.7 gm. This may increase to 8 gm. or even 12 gm. daily in diabetic patients. Simon[2] points out that high absolute values are quite constantly observed in diabetes, in which a daily elimination of from 4 to 5 gm. may be regarded as common. It is generally conceded that the relative increase of ammonia is more significant than variations in the absolute quantity. This is represented by the so-called ammonia quotient, i. e., the ammonia-nitrogen divided by the total nitrogen, and should always be determined whenever possible; it is normally from 3.5 to 5 per cent. In diabetic cases the ammonia quotient may rise to 40 or even 60 per cent. Goodall and Joslin[3] have recently made an extensive and valuable study of the ammonia output in diabetes, emphasizing its great importance. They conclude that quantities of ammonia reaching 5 gm. in twenty-four hours indicate a very severe form of diabetes, which usually proves fatal within a year, and that patients under 40 years of age tolerate an acidosis expressed in terms of 4 to 5 gm. ammonia far better than those above 50 years tolerate an acidosis of 2.5 to 4 gm. ammonia. Williams[4] states that the ammonia quotient may increase to 20 or even 40 per cent. in the pernicious vomiting of pregnancy and is an indication for emptying the uterus. In the case of nervous vomiting, reflex from the pelvis, and in eclampsia it is unchanged. The estimation of total nitrogen is not feasible clinically with existing methods, but, knowing the character of the diet, the absolute ammonia output alone is of very great value. The need for a simple method of estimation is obvious. The vacuum distillation methods of recent years represent great advances and are highly accurate, but they require time and facilities not possessed by the average clinical worker.

PRINCIPLE OF THE FORMALIN METHOD

An aqueous solution of an ammonium salt is treated with an excess of formalin and a few drops of phenolphthalein added as the indicator. It is now titrated with one-tenth normal sodium hydroxid, liberating ammonia, which reacts quantitatively with formalin to form hexamethylentetramine, which is neutral to phenolphthalein. The acid radical of the salt set free is titrated with the alkali, thus giving an index to the amount of ammonia present. This reaction has long been known in the literature.

PREVIOUS EXPERIMENTS

Ronchèse[5] first applied this principle to the estimation of ammonia in urine. Ten c.c. of urine were diluted to 50 c.c. with distilled water and titrated to the neutral point, using phenolphthalein as the indicator. Fifteen c.c. of 20 per cent. commercial formalin, made exactly neutral previously with sodium hydroxid, were then added, and the mixture then titrated with one-tenth normal sodium hydroxid. The second reading on the burette was reported as the number of cubic centimeters of decinormal ammonia in the sample. The method was checked by adding known quantities of ammonia to various urinary samples and it was claimed that quantitative recovery was the rule.

Repiton[6] has published a similar procedure in which acetaldehyde was substituted for the formalin; substantially the same claims were made for this process.

Malfatti[7] has recently reported a method essentially the same as the process of Ronchèse, but the degree of accuracy was tested with greater thoroughness. Controls were made with the methods both of Schlosing and Folin;[8] the formalin procedure showing a tendency to higher results. The influence of uric acid, urea, and creatinin on the titration was studied with negative results. No reference, however, was made to Ronchèse's work, and the latter[9] has called attention to this matter in a later article, emphasizing that Malfatti is not entitled to credit for the method.

Mathison[10] has recently modified this method by saturation of the urine with a neutral potassium oxalate before carrying out the titration, with a view to sharpening the end-point. Folin[11] first employed this salt to rule out the disturbing effects of ammonia salts and calcium phosphate in determining the end-point in the titration of urinary acidity, with phenolphthalein as the indicator. Mathison emphasizes the value of this modification. The results were checked by Shaffer's[12] method of vacuum distillation and found to be about 15 per cent. higher by the formalin process. He is unable to explain the discrepancy. Urea, uric acid, and creatinin were added to urine without affecting the ammonia values, thus in agreement with Malfatti's claim that these bodies are not sources of error.

PRESENT EXPERIMENTS

Several months ago I made a large number of titrations with various urinary samples, following the directions of Ronchèse and Malfatti. It was impossible to determine the end-point of the titration with any degree of sharpness, and the method was abandoned in this form. Cochineal and alizarin red were substituted as indicators for phenolphthalein, as they give sharp end-points in the presence of ammonia salts in aqueous distillates. They were abandoned as not sufficiently sensitive, even when the method was applied to chemically pure aqueous solutions of ammonia salts. The use of neutral potassium oxalate, as recommended by Folin, occurred to me in this connection before Mathison's paper appeared. The urine was saturated with the salt; the procedure otherwise was carried out exactly as described by the above authors. The end-point was now brought with a fair degree of sharpness; this improvement was particularly of advantage in deeply colored urines.

The method was applied to aqueous solutions of one-twentieth normal, one-tenth normal, and one-half normal ammonium chlorid with a resultant accuracy between 90 and 95 per cent. Known quanties of this salt were added to urine and recovered within the limits just stated. A series of estimations were carried out and controlled by Shaffer's vacuum distillation method. The data are assembled in the second and fourth columns of the accompanying table. The results of Shaffer's method average 20.33 per cent. higher, while Mathison obtained a corresponding figure of 15 per cent.

THE DETERMINATIONS OF AMMONIA

1 Sample of urine.	2 Formalin method uncleared. %	3 Formalin method cleared with lead. %	4 Shaffer's method. %
1	0.0586	0.0537	0.0507
2	0.0816	0.0705	0.0673
3	0.0782	0.0721	0.0697
4	0.0748	0.0736	0.0694
5	0.0591	0.0544	0.0501
6	0.0450	0.0382	0.0361
7	0.0599	0.0527	0.0499
8	0.0221	0.0162	0.0159
9	0.0629	0.0535	0.0507
10	0.0127	0.0102	0.0104
11	0.0559	0.0527	0.0504
12	0.0501	0.0425	0.0388
13	0.0476	0.0399	0.0354
14	0.0411	0.0348	0.0331
15	0.0642	0.0578	0.0544
16	0.0493	0.0461	0.0459
17	0.0331	0.0297	0.0253
18	0.0546	0.0535	0.0527
19	0.0433	0.0382	0.0367
20	0.0577	0.0534	0.0493
21	0.1470	0.1402	0.1309
22	0.0690	0.0620	0.0595
23	0.0476	0.0428	0.0408
24	0.0535	0.0476	0.0449

The sharpness of the end-point still left much to be desired, and it occurred to me that clearing the urine with subacetate of lead might be of advantage in removing interfering coloring matter before the titration. The excess of lead was removed by neutral potassium oxalate.

[12] Shaffer, P.: Am. Jour. Physiol., 1902, viii, 330.

The results were striking. The end-point of the titration was brought out with nearly the sharpness obtained in titrating a watery distillate with cochineal or alizarin red. Many samples after dilution were practically colorless, and in no case was there more than a slight tinge of pigment. Known amounts of ammonia added to the urine were recovered with the same degree of accuracy as without the modification.

The technic of the modified method is as follows:

About 60 c.c. of filtered urine are treated with 3 gm. of basic lead acetate, well stirred, allowed to stand a few minutes and filtered. The filtrate is treated with 2 gm. of neutral potassium oxalate, again well stirred and filtered. Ten c.c. of the clear filtrate are diluted to about 50 c.c. with distilled water and a few drops of 1 per cent. phenolphthalein added. The fluid will be slightly aklaline or acid; more frequently the latter. Fifteen gm. of neutral potassium oxalate are added, thoroughly stirred, and the specimen exactly neutralized with one-tenth normal sodium hydroxid or sulphuric acid; 20 c.c. of 20 per cent. commercial formalin, previously made neutral, are added and the solution again titrated with one-tenth decinormal sodium hydroxid. Every cubic centimeter of one-tenth normal sodium hydroxid corresponds to 0.0017 gm. ammonia. The burette reading of the second titration multiplied by this factor represents the amount of ammonia in 10 c.c. of urine. The quantity is then calculated on the basis of the twenty-four-hour volume.

The technic of this method should recommend itself to practitioners for its simplicity; an estimation can readily be made in duplicate in ten minutes. The accompanying table in Column 2 shows the data by the modified method, which averaged only 6 per cent. higher than the results by the Shaffer method. It is obvious that this difference would be of no clinical importance, for only large quantitative changes in the output of ammonia have significance clinically. Clearing with lead not only improves the end-point, but improves the accuracy of the method by nearly 15 per cent.

Sörensen[13] recently published a paper with an important bearing on the accuracy of the formalin method. He has demonstrated that formalin combines with amido-acids, liberating acid radicals which may be titrated, thus giving a measure as to the amount of amido-acids present. A number of acids, i. e., alanin, leucin, tyrosin, etc., were titrated, and, with the exception of tyrosin, were capable of quantitative determination. Obviously such bodies in the urine would be included in the ammonia determination and thus be a source of error. This, however, could not account for the difference between Columns 3 and 4 of the table, as amido-acids are not removed from the urine by basic lead acetate. Sörensen reports that uric acid reacts with formalin and this body is thrown out by the clearing reagent. Uric acid was estimated in a number of the samples referred to, but the quantity present accounted for only a part of the differences observed between Columns 1 and 2. Hippuric acid, which is not thrown down by clearing, was tested, but does not affect the formalin titration even when added in large amounts.

The important consideration clinically is the extent of the occurrence of amido-acids in the urine. Brugsch and Schittenhelm,[14] in reviewing the subject recently, state that glycocoll is the only amido-acid thus far demonstrated in normal urine and occurs in very slight amounts. Leucin and tyrosin have been shown in the cases of acute yellow atrophy, phosphorus-poisoning and in diabetic coma. Mathison says that it is just in those pathologic conditions when the output of ammonia is high that large quantities of amido-acids are excreted. These bodies replace a portion of urea, so their significance clinically is in the same direction as ammonia. If the formalin method gives the sum of ammonia and amido-acids, the ammonia could be estimated by Shaffer's vacuum distillation method and the amido-acids indirectly determined by difference.

A PLEA FOR THE MORE CAREFUL DIAGNOSIS AND TREATMENT OF FRACTURES OF THE EXTREMITIES *

E. DENEGRE MARTIN, M.D.
NEW ORLEANS

As in all other surgical conditions, great advancement has been made in the treatment of fractures. The suspension method of the lower extremities perfected by Hodgen and the ambulatory treatment suggested by Krause, Dollinger and others, have done much not only for the comfort of patients, but unquestionably have saved many an old sufferer from death by pneumonia. The introduction of anesthesia and the certainty of asepsis have reduced the mortality in compound fractures to practically *nil*. The advent of the x-ray has made a doubtful diagnosis a certainty and excellent results have been secured by this means in many apparently hopeless cases. It may, therefore, appear strange in the present-day advancement of surgical progress, when technic has reached almost a point of perfection, that one should be pleading for more thoroughness in so important a condition as the treatment of fractures. It is not that this branch of surgery has received less attention, for, thanks to Stimson, Scudder, Allis, Pilcher, Cabot, Hodgen, Whitman, Smith, Kocher, Korsch, Dollinger, Downey, and hundreds of others who have contributed so much to the literature, our technic is nearly perfect, but I have been forcibly impressed by the fact that we are treating to-day more deformed and ununited fractures as secondary conditions than any others in surgery. It strikes me that these bad results are due to one of several conditions; primarily, to our methods of treatment, and, secondarily, to the fact that this particular branch of surgery has not been assigned to its proper domain.

In regard to the first point, is it not a fact that students are taught to treat fractures from the benches? The subject is hurriedly gone over, probably a dozen or more fractures are demonstrated in one lecture, a number of intricate splints are exhibited, and reference is made to plaster of Paris as one of the materials to be used in the manufacture of splints. What is the result? Unless the student is fortunate in securing an interneship in some hospital, he goes out to treat fractures with a vague idea that it means a broken bone, and if he can only put it in position and hold it with some form of apparatus it will unite and that will be the end of it. If he should attempt to use plaster, of which he knows absolutely nothing, he has no means of telling whether it be good or bad, and the chances are that it will not set. The result is a deformed or ununited fracture.

In regard to the second point, there is no question that in this special line of work mechanical skill is required. How many physicians possess this? The orthopedist is the outcome of a demand for the correction of

deformities, most of which result from badly treated fractures. The orthopedist is, or should be, a mechanical surgeon; why not, therefore, in this era of specialists let him utilize his skill, not wholly for the correction of deformities, but for their prevention.

---

[13] Sörensen: Biochem. Ztschr., 1908, vii, 47.

[14] Brugsch, J., and Schittenhelm, A.: Lehrbuch klinischer Untersuchungsmethoden, 1908, pp. 463, 464 and 465.

* Read in the Section on Surgery of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

No inexperienced physician would attempt to do a laparotomy for some abdominal condition with which he was not familiar, and yet how many would think of referring a simple fracture to a surgeon? In the former case, life might be involved; in the latter, the worst that could happen would be an imperfect result, a crippled limb which the poor patient is convinced was the outcome of his misfortune and not the result of the faulty technic applied.

It is time for every practitioner to realize that, unless he has had some surgical experience and is equipped with an *x*-ray outfit, it is as much his duty, when possible, to refer these patients to properly qualified surgeons as other cases which he does not feel will fare well in his hands.

It is not my purpose to discuss the treatment of fractures, but I am glad to see so many medical men advocating the operative treatment. I see no reason why we should hesitate to expose a fracture at any time we fail to get good apposition. It is time that we should realize that the bony framework of the human body is its most important structure, and if this is injured at any point, or is so much out of place that muscular action is interfered with, we have a hopeless cripple on our hands; and I regret to say that in many instances the crippled condition is due not so much to the cause as to the treatment.

We hear many criticisms of the use of wire and staples in the treatment of ununited fractures, and numerous are the suggestions made to do away with the use of all foreign bodies. I believe that whenever it is possible to reduce a fracture and to hold it in position with a properly fitting splint it should be done, but I also believe that when there is danger of the fragments slipping the best results will be obtained by the use of wire or staples, even if these have to be removed later. My experience is that a staple is less liable to give trouble than wire and is much more efficient. For years I have used staples of different sizes made of piano wire, which can be driven into any bone, and these have never given trouble, unless infection followed, and they are always easy to remove when necessary.

In conclusion, I would suggest that we lay more stress on the importance of this branch of surgery, which furnishes material for more malpractice suits than any other, and is costing railroads and manufactories thousands of dollars annually.

ABSTRACT OF DISCUSSION

Dr. C. L. Scudder, Boston: The operative treatment of recent closed fractures is a very vital subject, surprisingly suggestive, full of interest to every one. We all believe in the operative treatment of certain fractures, provided the indications are unmistakable. Operating on freshly fractured bone is to-day safe if the operative technic is perfect. Osteitis and necrosis do not commonly follow properly placed direct fixative materials—wire, nails, pegs, plates or screws. Union of the fracture is usually facilitated and not delayed by operation. Damage to the soft parts extensive enough to cause postoperative difficulties may be avoided and is not a menace. The local conditions surrounding recent fracture are quite different from those discovered at the seat of an old fracture.

In our enthusiasm for operative victories we must stop and ask ourselves, are we securing from the non-operative treatment all that we possibly can? When should we employ operative measures? What should be the general indications for operation?

Deficiencies in non-operative treatment, which unquestionably do exist, should be remedied, not by operating more frequently but by exercising greater care in the employment of *the fundamental principles recognized the world over* as underlying the treatment of all fractures, namely, general anesthesia, traction, counter-traction; pressure, counter-pressure; the exact application of anatomic knowledge; immobilization; the comparative use of the Roentgen ray; massage; the care of joints adjacent to the injury, and, ultimately, the securing approximately anatomic form and perfect function. Whenever and wherever these basic principles are applied intelligently and consistently, the results are uniformly good and the operative margin is then narrow. Bardenheuer, in Germany, has demonstrated the efficiency of non-operative methods. Even though Bardenheuer's details may be too cumbersome for general use, he has proved that results following the consistent employment of non-operative methods are satisfactory. That non-operative measures are efficient in the treatment of the vast majority of fractures has been proved in this country over and over again in hospital and private practice. Many facts in corroboration of this statement have been recently collected by DaCosta and others, and are still being assembled, and are worthy of consideration. I want to dissuade any one from believing that an anatomically perfect result following a fractured bone is absolutely necessary to a functionally useful limb, or is necessary to the individual. Approximate reduction, that is, non-anatomic, is followed by union and by a functionally useful part, and *by no apparent deformity to the* patient or his non-professional friends.

Stimson recently said regarding this matter: "Irregularities of outline are functionally and cosmetically unimportant in the great majority of cases in which proper non-operative treatment has been used." *Anatomic results are ideal and* theoretically desirable. Practically, they are unessential. The ideal treatment may not be the most expedient. Operation is often contraindicated chiefly because it is unnecessary. It must be remembered that the results of operative treatment *may not be more satisfactory than are the results from non-*operative treatment. Operation does not carry with it or imply the guarantee of a perfect anatomic result. The majority of simple or closed fractures can be satisfactorily treated by non-operative methods. The broad indication for operation, in my opinion, on recent closed fractures, in the absence of great damage to soft parts, including vessels and nerves, is the inability to bring fragments into apposition and into good alignment. Let all surgeons bestow as much thought and personal consideration on the non-operative methods in the treatment of fractured bone as the importance of the subject demands, and our non-operative results, good as they are, will improve, and the number of operable cases will increase slowly and only for good and sufficient reasons.

Dr. W. Lemoyne Wills, Los Angeles, Cal.: It was my good fortune four years ago to see Lambotte demonstrate his method for fixation of fractures on a cadaver at the Brussels congress, and to see his convalescent patients at Stuyvensburg Hospital at Antwerp next day. For two years past I have used this method and appliance. I have had seven cases of fracture of femur and two of humerus. Of these cases I have had five simple fractures in mid-thigh and near the knee-joint, varying from thirty hours to two weeks in time from injury to operation, two ununited fractures each six weeks old with large amounts of callus and faulty angulation of fragments. Two fractures of humerus were six weeks and three months old, respectively; the latter was an old comminuted, infected gunshot fracture of the humerus with complete musculospiral paralysis. On this case I put a half-sized apparatus and relieved the pressure on the nerve which was between ends at point of fracture; the patient is making a fine recovery. Absolute fixation is desired most of all. With the Lambotte apparatus the leg can be lifted by the heel, and when union has taken place all foreign material is removed. Patients differ greatly in rapidity of callus formation, usually sufficient has been thrown out to permit safe removal of the apparatus in from four to seven weeks. The sooner the drills are out the better. The drill holes soon close and give no trouble. We all know what unsatisfactory results are obtained by the commonly used closed treatment, and by the suturing and wiring of the fragments, when there may be shortening from one-half to one and a half or two inches. I have shortening, in only one case—one-fourth of an inch—and that because the man disobeyed orders and put weight too soon on a soft callus. After absolute fixation the chief advantages are: the ability to inspect the wound every day; less injury to the periosteum than by any other operative method; and more rapid and normal callus formation and union. The first dressing (removed in twenty-four hours) will be found saturated with serum and blood. I use two or three drains, which are removed in two or three days, leaving the wound perfectly dry. It is better to have the serum and blood out than inside congesting the damaged tissues. This is really an ambulatory method, enabling the patient to be put in a wheeled chair, after ten days, and kept in the open air. Of course, absolute asepsis must be preserved. I have had infection in two cases, but that was due to severe bruising and crushing of muscles at time of injury, and the delay in operation, two weeks having elapsed.

Dr. A. J. Ochsner, Chicago: My ideas on treatment of fractures are pronounced. In certain fractures, like that of the patella, the anatomic conditions are such that the results, even with the best non-operative treatment, must be bad. There are other conditions in which these conditions must be bad, but with the exception of these conditions, if we employ certain definite principles the results must be good. Of course, if we do not teach our assistants that a fracture held by plaster-of Paris in a deformed position is sure to heal in that position, we must expect to get bad results. If we do not teach our assistants the proper use of splints and the proper methods of reduction of fractures we must not look for good results. But if a surgeon with good judgment and with experience in these principles will employ them, the number of cases in which the operative treatment should be employed must be very small.

Dr. Leonard Freeman, Denver: There are two kinds of fractures which seem to demand operation, providing the surroundings are perfect, and the operator is competent. In one kind we are unable to reduce the fragments at all; in the other, although we are able to place the bones in apposition, they have little or no tendency to stay there. I desire to exhibit a clamp which I have devised for holding fractures of the latter class which cannot be controlled by ordinary means. It is not so much the clamp to which I wish to call attention, but rather the method of its application. The clamp is simple; it consists of two steel strips fastened together by screws which can be tightened with a key. (Figs. 1 and 2 and Fig. 3a.) The essential feature is that these strips of steel are lined with soft wood. From two to four long screws, as required, are inserted in the end of the fragments and allowed to project beyond the skin. The screws are then clamped together by means of the wood-lined steel strips, the wood holding them firmly and preventing slipping. There is no question as to the effectiveness of the clamp when it is once in place. The problem is to use it in recent fractures without making a large wound and without extensive injury to the tissues—in other words, without exposing the patient to the danger of a severe operation. This could readily be done if it were possible to insert the screws into the bone through small incisions in the skin, adjust the fragments, and then clamp the screws; but any one who attempts to do this without proper apparatus will find that the drill is apt to slip, and that when an effort is made to find the hole with the end of the screw after removing the drill it cannot be done owing to the intervention of the soft parts. Drills cannot be left in place as substitutes for screws, because they do not fit tightly enough. I have overcome this difficulty by using a small steel tube which is provided at one end with sharp teeth. Into this tube is placed an obturator (Fig. 3c) with a blunt point which obscures the teeth and enables one to slip a screw (Fig. 3e) through a small incision in the skin and through the soft parts to the bone. The obturator is then removed and the tube tapped down so that the teeth engage in the periosteum, thus preventing slipping. A drill (Fig. 3d) is then introduced through the tube after taking out the obturator. The drill has an adjustable shoulder so that it will remain central within the tube. A hole is then bored into the bone, the drill is removed, and a screw can easily be introduced, the tube being pulled out over the screw. In this way as many screws as necessary can be employed and left to protrude through small openings in the skin which produce but insignificant scars. This apparatus can be used to great advantage in certain fractures. I have employed it in fracture of the jaw near the angle, where it is difficult to keep the jaw from dropping backward in spite of various uncomfortable splints which have been devised. By using two screws, one in each fragment, and clamping them together on the outside, the jaw is easily and perfectly held in place. Fractures of the clavicle can also be handled in this manner, as can also oblique breaks of the tibia and fractures of the humerus and patella. I do not believe that anything is added to the danger of infection, especially if the screws are placed far enough from the break and if proper asepsis is employed, as they soon become effectually walled off from the surrounding tissues.

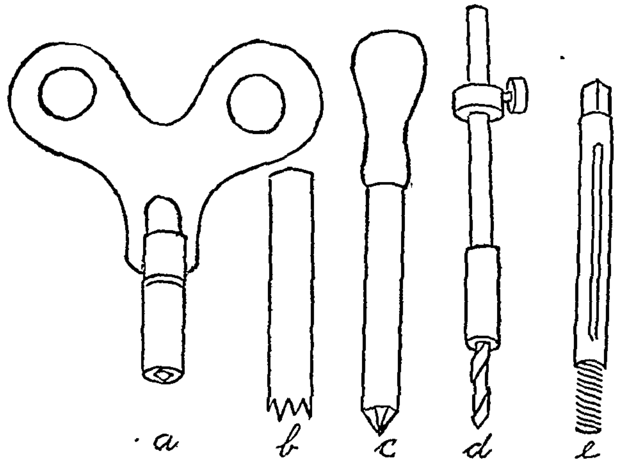

Fig. 3.

Dr. John B. Walker, New York City: I believe that our knowledge of the treatment of fractures in America has not advanced so rapidly as it has in the treatment of abdominal and other conditions. A few years ago a leading London surgeon attempted to ascertain what was the ultimate or end-result in these fracture cases, and he sent out many letters to which he received 400 replies. He found that what was called satisfactory in London was not so regarded in the outlying districts. In the large cities the duration of the treatment of a fracture of the femur was from four to six months, whereas in the outlying districts it was from six to nine months. Since the introduction of the Roentgen ray this matter of the proper

deformities, most of which result from badly treated fractures. The orthopedist is, or should be, a mechanical surgeon; why not, therefore, in this era of specialists let him utilize his skill, not wholly for the correction of deformities, but for their prevention.

No inexperienced physician would attempt to do a laparotomy for some abdominal condition with which he was not familiar, and yet how many would think of referring a simple fracture to a surgeon? In the former case, life might be involved; in the latter, the worst that could happen would be an imperfect result, a crippled limb which the poor patient is convinced was the outcome of his misfortune and not the result of the faulty technic applied.

It is time for every practitioner to realize that, unless he has had some surgical experience and is equipped with an *x*-ray outfit, it is as much his duty, when possible, to refer these patients to properly qualified surgeons as other cases which he does not feel will fare well in his hands.

The local conditions surrounding recent fracture are quite different from those discovered at the seat of an old fracture.

In our enthusiasm for operative victories we must stop and ask ourselves, are we securing from the non-operative treatment all that we possibly can? When should we employ operative measures? What should be the general indications for operation?

Deficiencies in non-operative treatment, which unquestionably do exist, should be remedied, not by operating more frequently but by exercising greater care in the employment of the fundamental principles recognized the world over as underlying the treatment of all fractures, namely, general anesthesia, traction, counter-traction; pressure, counter-pressure; the exact application of anatomic knowledge; immobilization; the comparative use of the Roentgen ray; massage; the care of joints adjacent to the injury, and, ultimately, the securing approximately anatomic form and perfect function. Whenever and wherever these basic principles are applied intelligently and consistently, the results are uniformly good and the operative margin is then narrow. Bardenheuer, in Germany, has demonstrated the efficiency of non-operative methods. Even though Bardenheuer's details may be too cumbersome for general use, he has proved that results following the consistent employment of non-operative methods are satisfactory. That non-operative measures are efficient in the treatment of the vast majority of fractures has been proved in this country over and over again in hospital and private practice. Many facts in corroboration of this statement have been recently collected by DaCosta and others, and are still being assembled, and are worthy of consideration. I want to dissuade any one from believing that an anatomically perfect result following a fractured bone is absolutely necessary to a functionally useful limb, or is necessary to the individual. Approximate reduction, that is, non-anatomic, is followed by union and by a functionally useful part, and by no apparent deformity to the patient or his non-professional friends.

Stimson recently said regarding this matter: "Irregularities of outline are functionally and cosmetically unimportant in the great majority of cases in which proper non-operative treatment has been used." Anatomic results are ideal and theoretically desirable. Practically, they are unessential. The ideal treatment may not be the most expedient. Operation is often contraindicated chiefly because it is unnecessary. It must be remembered that the results of operative treatment may not be more satisfactory than are the results from non-operative treatment. Operation does not carry with it or imply the guarantee of a perfect anatomic result. The majority of simple or closed fractures can be satisfactorily treated by non-operative methods. The broad indication for operation, in my opinion, on recent closed fractures, in the absence of great damage to soft parts, including vessels and nerves, is the inability to bring fragments into apposition and into good alignment. Let all surgeons bestow as much thought and personal consideration on the non-operative methods in the treatment of fractured bone as the importance of the subject demands, and our non-operative results, good as they are, will improve, and the number of operable cases will increase slowly and only for good and sufficient reasons.

Dr. W. Lemoyne Wills, Los Angeles, Cal.: It was my good fortune four years ago to see Lambotte demonstrate his method for fixation of fractures on a cadaver at the Brussels congress, and to see his convalescent patients at Stuyvensburg Hospital at Antwerp next day. For two years past I have used this method and appliance. I have had seven cases of fracture of femur and two of humerus. Of these cases I have had five simple fractures in mid-thigh and near the knee-joint, varying from thirty hours to two weeks in time from injury to operation, two ununited fractures each six weeks old with large amounts of callus and faulty angulation of fragments. Two fractures of humerus were six weeks and three months old, respectively; the latter was an old comminuted, infected gunshot fracture of the humerus with complete musculospiral paralysis. On this case I put a half-sized apparatus and relieved the pressure on the nerve which was between ends at point of fracture; the patient is making a fine recovery. Absolute fixation is desired most of all. With the Lambotte apparatus the leg can be lifted by the heel, and when union has taken place all foreign material is removed. Patients differ greatly in rapidity of callus formation, usually sufficient has been thrown out to permit safe removal of the apparatus in from four to seven weeks. The sooner the drills are out the fragments. Judging by this simple standard, there is no question that a vast number, the majority, of fractures of the extremities can be successfully treated without operation. It is only right that the art of bone-setting by bloodless manipulation should be cultivated and encouraged more than ever as an essential part of the surgeon's training. On the other hand, when it is evident that reduction is impossible and that deformity with impaired function is unavoidable in any given case of fracture, there should be no hesitation in resorting at once to the open treatment, provided all other conditions, including the operator's training, are favorable to the procedure. In conclusion, I would ask: What are we to do in operative cases in which a perfect result is obtained, a real cabinet-maker's approximation, and yet in which callus totally fails and there is no ossification? This failure of repair which I have observed in operative cases, and especially after wiring, creates a serious problem that is not solved by further operation, additional traumatism, nor by Bier's blood injections at the seat of fracture. In these cases, what will accomplish the desired result? Will orthopedic "walking" braces which do not constrict the limb, and which permit the systematic application of massage combined with hot air hyperemia? It is the walking splint, however, that is the most effective, and, in view of the not infrequent failure of union after operation, I am glad to commend the ambulant orthopedic splint as a reliable treatment for this deplorable condition.

Dr. DeForest Willard, Philadelphia: Surgeons differ widely in their advocacy of operative or non-operative treatment in fractures. Dr. Martin called attention to the question of diagnosis. There is at present no reason for failing to know whether we have succeeded in the replacement of fracture. The Roentgen ray will tell us all this. It is not only necessary to reduce the fracture, but to keep it reduced. There are certainly a large number of simple fractures that do not require operative treatment, but there are cases in which it is necessary to resort to operation, *i. e.,* those in which reduction and retention are impossible and especially delayed union, non-union, compound fractures and comminuted fractures. Fracture patients often come to the hospital and they are not seen by the surgeon at all. They are treated by the house officers; they are sometimes treated carelessly, and a bad result is sure to follow. We all have reason to know the annoyance that comes from a malpractice suit, and the Roentgen ray is adding to our troubles because while many cases are functionally perfect, they are not anatomically perfect and a jury is readily influenced. The Roentgenogram is only a shadow and not the thing itself. Look at your own shadow as you are walking on the pavement. It is not at all like yourself. In comminuted and ununited fractures I have tried wires, staples, screws, plates, clamps and everything else. We all know how often we are obliged afterward to cut down and remove these substances; therefore, whenever it is possible, I use chromicized catgut rather than any other foreign body. Magnuson has shown that metal-headed ivory screws that can be cut off on a level with the periosteum can be inserted into the bone and soon become a part of it. I believe that the use of such ivory screws will revolutionize the treatment of ununited fractures.

Dr. Charles E. Thompson, Scranton, Pa.: Dr. Martin said that the fracture might slip, and stopped there. We must not be discouraged because our fractures slip. We must reduce them again, until we retain them in proper position. Dr. Ochsner spoke about the bad results obtained in the treatment of fractures in the general hospitals, but nothing has been said about the bad results obtained out in the hills by the general practitioners, nor has anything been said about the cause of these bad results. I hope college professors will tell us why these general practitioners cannot be taught to reduce fractures. Of all the delusions and snares, perpetrated on an unsuspecting profession, Buck's extension apparatus is the worst. Dr. Scudder told us something about the reduction of fractures but did not go far enough. If a fracture, say of the femur, becomes displaced after reduction, in my experience the most common cause of displacement is a muscular spasm occurring during sleep. If the fragments cannot be retained in a direct line I have frequently succeeded in retaining them at an angle, letting that deformity prevail until some union has taken place, when the bone can be very easily set in a straight line. The difficulty of having plaster set and stay set can be obviated by using crinolin sized in starch. If the bone cannot be held in proper position, a slight amount of lateral pressure, such as placing a wedge of cotton or gauze on the inside of the plaster on the third or fourth day after reduction, will hold the bones in perfect apposition. If this method fails, I have in a few cases succeeded by putting on a counter-extension transversely, and holding up the bone in the same direction, where there was a great tendency to displacement in an upward or downward direction. In another case, a compound fracture of the tibia having failed to be retained in position by ordinary methods, I inserted an osteotome, and securing a slight leverage between the ends of the bones, held then in place and had an assistant hold the osteotome in position; I then incorporated osteotome and assistant's hands in the cast. The assistant's hand was removed after the cast was hard, after the patient was put to bed; the osteotome was removed the next day. The result was ideal.

Dr. Robert F. Weir, New York City: We have been told, and correctly so, that fractures are hard things to treat. They tell us also that in the hospitals they are badly treated because the juvenile intern does the treating. That is true, but there is another reason which has not been mentioned why there are so many cases of malpractice. Malpractice suits are brought against the physicians who are only occasionally surgeons. If surgeons say that it is hard to treat a fracture, how can the ordinary practitioner expect to succeed in doing so? He does not attempt to do an abdominal operation, but he does not stop at treating a fracture, which we all know is a very hard thing to manage successfully. The majority of cases should be judged not by hospital treatment, not by the treatment given them by the general practitioner, who, with the aid of the misinterpreted x-ray picture, is so frequently sued, but by the outcome of the cases treated by a competent surgeon, cases that the latter treats in his private practice. As I look back on my cases of fracture, I must say that the majority of them have terminated in a very satisfactory manner. I do not mean to say that some of the patients have not had deformities, but the individuals have been able to go about and to use the extremity. The result has been satisfactory and would more than counterbalance the risk of an open operation. A Philadelphia surgeon many years ago remarked that antiseptic surgery is not cock-sure surgery even in the hands of the best men.. This is yet true. If I had a fracture of the patella, I certainly would not have my knee-joint opened and the fracture sewn up. I would take my chances the other way and believe that I would come out pretty well. King Edward's patella was treated bloodlessly and wisely.

Infant Mortality.—The young of all animals are more susceptible than the adult to the influence of environment and the approach of death. Owing to the long duration of the period of infancy in human beings as compared to that of the lower animals in general, it is obvious that the opportunity of environment to react on our development is enormously increased over that afforded in the case of other living beings. Hence it is inevitable that even under the most favorable circumstances, the deaths of infants will furnish a large contribution to the bills of mortality. But when it can be said of a city, as it can to-day be truly said of Boston, that, "the new-born child within its gates has less chance than a man of 90 of living for a week, less chance of living through a year than a man of four-score," there surely is connoted a prevalence in that city of those causes and conditions which in the long run determine a degeneration of the race. Poverty alone is not responsible. In many poor communities the infant mortality is low. Housing and external environment alone do not produce this evil, for under some of the worst external conditions in the world it is absent. The chief cause of infant mortality is to be found in that component factor of its environment which is more potent than any other of influencing the future development and determining the fate of the new-born babe.—J. M. Connolly in *Hygiene and Physical Education.*

treatment of a fracture has become a personal and important one to many surgeons. Last year the largest liability accident insurance company in this country showed that out of 100 suits for damages, 75 per cent. were brought on account of surgical conditions, and the remaining 25 per cent. on account of medical conditions. Of the damage suits brought against surgeons, 75 per cent. were on account of deformity following the treatment of a fracture. Only a year ago Mr. Lynn Thomas, a British surgeon, was sued in a case of fracture of the surgical neck of the humerus. The case passed from one court to another and at the end of a year the damages allowed were over $20,000. As Dr. Ochsner said, the statistics in our large hospitals show that, as a rule, fractures are treated by young men who do not receive any instruction from the surgeons but from previous house officers. In the large New York hospitals, when a fracture of the neck of the femur comes in, for instance, the patient has to stay for twenty-four or forty-eight hours, when he is sent to other hospitals because the hospital wants to get rid of these cases. The result is that these patients come in with much shortening and go out with considerably more shortening.

Dr. J. B. Murphy, Chicago: That the results from the treatment of fractures in the large hospitals are not satisfactory is an admitted fact. This is due to two elements; first, the neglect of these cases by the attending surgeon; and second, the imperfect understanding of the conditions of the individual fracture by the medical profession. Bad results in their order of frequency are, in Colles', in Potts', in every fracture of the neck of the femur, in fractures of the patella and in those of the olecranon. Take, for instance, Colles' fracture. The bad results seen here are not due to the fact that the bones cannot be kept in position, but to the fact that the bones are not properly replaced in over 95 per cent. of the cases. The reduction of a Colles' fracture involves a special technic, one different from that of the reduction of any of the other common fractures of the body. The fracture occurs in a certain line extending from in front upward and backward. The lower fragment is displaced upward on the posterior surface of the radius. The *method of reduction is simple, easy,* and uniformly neglected. First, place the thumb of the right hand on the distal fragment and put the thumb of the left hand on the proximal fragment, increasing the deformity by pressing both thumbs forward to unlock the fragments. As soon as they are unlocked, place the end of the left thumb on the nail of the right thumb and press the lower fragment forcibly downward, then reverse the pressure by flexing the patient's hand forcibly forward, and the fragments will fall into position easily and will remain there. Afterward, all that is needed is to put on the simplest kind of plaster of Paris support over the wrist. If the deformity does not remain reduced, it is because it has not been reduced properly. If the pain is severe for from twelve to twenty-four hours it indicates that the reduction is not complete.

The types that must come to operation to get good results are, first, fractures of the neck of the femur, not in old people past sixty, but in younger people who do have fractures of the neck of the femur by direct or indirect violence. It is only by inspection and careful analysis of cases and by fixing these fragments that one can reduce the deformity and keep the fragments in apposition. In fractures of the neck of the femur close to the head a very important principle is involved; that is, the presence in the proximal fragment of any osteogenetic cells for the reproduction of the bone from the head side.

The principle of the apparatus exhibited by Dr. Wills and the one by Dr. Freeman, by which one can do the work without coming in contact with the traumatized area, thus avoiding exposure to infection, is an important one and should be utilized on all occasions when the fragments can be apposed satisfactorily. One should not operate immediately after the fracture, because the tissues are then in a condition of least resistance. Operation should be postponed until an effort at regeneration of the traumatized tissues has taken place. One can do an enormous amount of work on the fifth, tenth or fifteenth day without danger of infection that could not be done on the first or second day after the accident. The lymph spaces have become cofferdammed and the new capillaries are developed to the greatest resistance against microbic invasion.

Dr. Charles A. Powers, Denver: I believe that open operation in simple fracture will be performed more often than it has in the past, but also that open operation in simple fractures will be the exception rather than the rule. As I look back over my own results in simple fractures treated without operation I feel that they have generally been satisfactory. I do *not think the results in these fractures, when carefully treated* by established methods, are notoriously bad. I am entirely in accord with Dr. Scudder. He expressed my position clearly and thoughtfully. Further, Dr. Ochsner is right when he says that on our routine hospital work we are too prone to leave the treatment of these important cases to interns of but little experience. If we pay proper attention to suitable nonoperative management we will have fewer cases which demand operation.

Dr. W. L. Estes, South Bethlehem, Pa.: While I believe that in this matter we should be rather conservative, there are some fractures that, one might say, must almost invariably be treated by the open method. I have come to the conclusion as the result of considerable experience that there are certain localities where certain fractures require an open operation. The first of these is fracture in almost any part of the shaft of the tibia, when the fracture is very oblique, with no shoulder to hold it, making it impossible to keep the fragments in position by any ordinary mechanical means. My observation of the result of other surgeons' work and my own experience has taught me that no splint or mechanical contrivance will accurately reduce and retain these fractures in proper apposition without the open method. In this day of the *x*-ray not only must the usefulness of the limb be thought of, but also the cosmetic effect. The public demands that we treat these fractures of the extremity in a way to retain the appearance as well as the usefulness of the limb. To do this it is necessary that we perform an operation when the condition and surroundings of the patient are favorable. In regard to methods of fixing the fragments in an open operation, it does *not matter so much what apparatus* we use so long as we do the work under proper asepsis. Either a clamp, or a screw, or a splint, applied directly to the bone, will answer the purpose. I am opposed to any method, however, which will not enable one to see whether the fragments are in apposition. One may think that he has the bones in apposition, and put on a splint, but when the *x*-ray is used he finds, much to his surprise, that there is malposition. Hence the importance of an incision down to the seat of fracture, complete exposure and accurate coaptation of the fragments under the eye and then firm fixation.

Another fracture which should be treated by the open method is fracture of the junction of the upper and middle thirds of the humerus, where the musculospiral nerve is so apt to be injured. The danger of the injury is in proportion to the violence that has been done by the ends of the fractured bone. The nerve may not give any evidence of injury immediately, but within two weeks there may be paralysis. The explanation of this late development is that one end of the displaced fragments may press against the nerve, and the developing callus does the rest. Another fracture which requires the open method is that of the inferior maxilla. These fractures are nearly always compound, and they require drainage as *well as accurate replacement and fixation, hence* the open method should be employed.

Dr. Rudolph Matas, New Orleans: It does not follow that all fractures are better treated by operative methods or that good results cannot be obtained by bloodless manipulations. Surely practitioners of surgery cannot accept the *x*-ray standards of bone setting as the sole and absolute criteria of successful treatment. We who teach surgery, while fully recognizing the great advances brought about in the treatment of fractures by open methods of reduction and fixation, must remain in sympathy with the view which holds that when a broken bone is set without any visible deformity and is followed by no abnormal disability, such a result must be regarded as a good result—even though the *x*-ray may show some displacement or imperfect apposition of the fragments. Judging by this simple standard, there is no question that a vast number, the majority, of fractures of the extremities can be successfully treated without operation. It is only right that the art of bone-setting by bloodless manipulation should be cultivated and encouraged more than ever as an essential part of the surgeon's training. On the other hand, when it is evident that reduction is impossible and that deformity with impaired function is unavoidable in any given case of fracture, there should be no hesitation in resorting at once to the open treatment, provided all other conditions, including the operator's training, are favorable to the procedure. In conclusion, I would ask: What are we to do in operative cases in which a perfect result is obtained, a real cabinet-maker's approximation, and yet in which callus totally fails and there is no ossification? This failure of repair which I have observed in operative cases, and especially after wiring, creates a serious problem that is not solved by further operation, additional traumatism, nor by Bier's blood injections at the seat of fracture. In these cases, what will accomplish the desired result? Will orthopedic "walking" braces which do not constrict the limb, and which permit the systematic application of massage combined with hot air hyperemia? It is the walking splint, however, that is the most effective, and, in view of the not infrequent failure of union after operation, I am glad to commend the ambulant orthopedic splint as a reliable treatment for this deplorable condition.

DR. DEFOREST WILLARD, Philadelphia: Surgeons differ widely in their advocacy of operative or non-operative treatment in fractures. Dr. Martin called attention to the question of diagnosis. There is at present no reason for failing to know whether we have succeeded in the replacement of fracture. The Roentgen ray will tell us all this. It is not only necessary to reduce the fracture, but to keep it reduced. There are certainly a large number of simple fractures that do not require operative treatment, but there are cases in which it is necessary to resort to operation, *i. e.*, those in which reduction and retention are impossible and especially delayed union, non-union, compound fractures and comminuted fractures. Fracture patients often come to the hospital and they are not seen by the surgeon at all. They are treated by the house officers; they are sometimes treated carelessly, and a bad result is sure to follow. We all have reason to know the annoyance that comes from a malpractice suit, and the Roentgen ray is adding to our troubles because while many cases are functionally perfect, they are not anatomically perfect and a jury is readily influenced. The Roentgenogram is only a shadow and not the thing itself. Look at your own shadow as you are walking on the pavement. It is not at all like yourself. M. Connolly in *Hygiene and Physical Education.*

BRAIN TUMOR*

WILLIAM G. SPILLER, M.D.

Professor of Neuropathology and Associate Professor of Neurology in the University of Pennsylvania

PHILADELPHIA

During the past year I have had the opportunity to observe a number of cases of brain tumor, certain features of which seem to me worthy of discussion. Especially noteworthy are the importance of gradually developing hemiplegia, the slow appearance of papilledema in certain cases of glioma, and later its remarkably rapid development, the resemblance of tumor of the pons to tumor of the Gasserian ganglion, and the signs of tumor of the occipital lobe, especially the dissociation of the color-sense in tumor of the left occipital lobe.

DIAGNOSIS OF BRAIN TUMOR

The credit for pointing out that progressive hemiplegia without other symptoms is diagnostic of brain tumor seems to belong to R. T. Williamson. In his paper[1] he states that it is well known that when hemiplegia is produced by a tumor in the motor cortex or white matter of one cerebral hemisphere the onset of the paralysis is usually very gradual. Day by day, and week by week, the loss of power becomes more and more marked. It may be weeks, or a few months, before the paralysis is complete. It is not so well known, he states, that progressive hemiplegia of the nature just described is an almost certain sign of brain tumor, even in the absence of optic neuritis, headache, and vomiting (provided there are no indications of cerebral abscess). Williamson reports three cases of brain tumor in which the hemiplegia developed very gradually, and in all three papilledema was absent. In the first case headache and vomiting were present; in the second case these two symptoms were absent for a long period; in the third case they were absent altogether. He refers to a similar case observed by him ten years previously. He expresses his views very clearly: "Provided there are no indications of cerebral abscess, progressive hemiplegia, or hemiplegia of gradual onset, in which weeks or a few months elapse before the paralysis is complete, may be regarded as strong evidence of cerebral tumor, even when optic neuritis is absent, or when optic neuritis, headache, and vomiting are all absent."

I can not refrain from stating that Williamson expresses his opinion somewhat too forcibly. A gradually developing hemiplegia I have seen as a symptom of polioencephalitis. A child recently under my care presented symptoms suggestive of brain tumor. An operation was performed at my request by Dr. Frazier and a portion of the cortex was removed, as at the operation it resembled tumor tissue. It proved to be the seat of polioencephalitis. Six weeks before the child came under my observation the right lower limb began to get weak, and one week later the right upper limb began to grow weak. The hemiparesis became gradually worse. The case I shall probably report in detail, and merely wish to call attention here to the fact that polioencephalitis as well as tumor may cause a gradually developing hemiplegia. The latter lesion is, of course, of much more frequent occurrence than the former.

Souques[2] also has recently written on gradually developing hemiplegia as a sign of tumor.

Cortical meningitis may cause a gradually developing hemiplegia, and the meningitis may be purulent or of other type. I have recently seen a case with Dr. W. G. Shields, Jr., and Dr. J. A. Hearst in which paralysis of the left lower limb, almost confined to the part below the knee, developed one day, and paralysis of the left upper limb and left side of the face did not appear until two days later. An operation by Dr. Edward Martin revealed a purulent meningitis, apparently confined to the region of the center for the lower limb. The paralysis in such a case, however, is likely to be of more rapid development than when caused by tumor.

The gradual development of hemiplegia was present in several of the cases mentioned in this paper. It was especially striking in Case 1, and, indeed, because of it I made the diagnosis of a probable tumor of the brain at my first examination of the patient. A hemiplegia had developed very gradually during a period of about six weeks, and there was at no time a sudden increase in the paralysis. Even within three days of death no changes in the eyegrounds were observed in an examination by Dr. de Schweinitz. A large tumor was found in the optic thalamus and internal capsule, and had undergone cystic degeneration. It had evidently caused no increase of intracranial pressure. Cases such as this and Cases 2 and 3 indicate that the production of papilledema by toxic substances alone in brain tumor is questionable. In all these cases the tumor was large, and yet papilledema did not occur, in two cases and developed only late in the other, probably because there was no great increase of intracranial pressure.

In Case 2 a gradually developing hemiplegia was observed, and yet the tumor did not extend to the internal capsule. Vascular changes in the internal capsule at a distance from the tumor caused the hemiplegia, as determined by the examination of certain sections given by me to Dr. Byrnes for this purpose. The importance of this finding is in the demonstration that a gradually developing hemiplegia in brain tumor does not imply necessarily that the tumor has extended to the internal capsule. The examination of the brain with the clinical notes in mind was a surprise to me, as to the naked eye no implication of the internal capsule could be detected, and the tumor evidently did not extend so far forward from the occipital lobe. Dr. Byrnes[3] has referred to these findings in another paper.

A gradually developing hemiplegia was observed also in Case 4, but the patient was not seen by me until the symptoms were far advanced, and it was uncertain how much reliance could be placed on the statements.

In a case seen by me in consultation with Dr. Babcock a diagnosis of brachial plexus palsy had been made at first, because the palsy seemed at that time to be confined to the upper limb. At the time I saw the patient the lower limb had also become affected, and other symptoms made the diagnosis of tumor a probable one. A cortical tumor was found by Dr. Babcock at operation.

I have in two instances known thrombosis of the middle cerebral artery to cause a gradual increase in the symptoms as seen in tumor, but when thrombosis is the cause the development of the symptoms is likely to be somewhat different. A partial palsy, or other symptoms indicative of brain lesion, may develop within a

short time, and then the symptom-complex may be arrested for some time, possibly several weeks, until the thrombus extends to one or more branches of the vessel previously affected, when additional palsy appears, but usually more rapidly than is seen when a tumor is the cause of the weakness. Occasionally a tumor may produce a very rapid palsy, as when a hemorrhage implicates the growth or when a glioma has destroyed many of the axis cylinders within the tumor but has left enough for the discharge of function, and suddenly, by edema or other cause, the impaired fibers become insufficient.

A peculiar symptom, present in Case 3, I have observed in two other cases of brain tumor, viz., intense hunger. Mrs. Y was hungry all the time and had a "most vigorous appetite," in the words of her friends. In another case a note was made that the patient had a voracious appetite. The intense hunger is not confined to tumor cases. The character of the tumor seems to have no bearing in the production of this symptom, nor does its location seem to have much importance.

Mrs. Y. (Case 3) also complained of pain and throbbing extending down the neck to the shoulders. Pain from tumor of the brain may be felt in the neck. This neck pain was very pronounced in a case reported by me some years ago, and in that case the tumor was at the foramen magnum and extended downward on the cord the distance of several cervical segments. Why pain should be felt in the neck from a tumor of the brain is not clearly understood, any more than is the related symptom of stiffness of the neck observed sometimes in cases of brain tumor, as in Cases 1, 2 and 4, in which rigidity of the neck muscles was caused by a tumor of the optic thalamus, by a tumor of the occipital lobe, and by a tumor of the region posterior to the optic thalamus. So far as I am able to determine, pain radiating down the neck and stiffness of the neck are not of localizing value.

The slow development of papilledema in glioma is worthy of comment. It may be absent throughout the disease, even when the tumor is large, as in Case 2, in which almost the entire occipital lobe of one side was occupied by a tumor, or in Case 3, in which it developed late, and after the tumor had attained a very large size. The latter case demonstrated another interesting phenomenon, viz., the occasionally extraordinarily rapid development of papilledema in brain tumor, even though it may be late in appearing. This patient was found on March 21 to have normal eyegrounds; on April 6 Dr. Thorington noticed for the first time that the nasal side of each disc had begun to be elevated and to be indistinct in outline, and that the retinal veins were enlarging. On April 13 he found the swelling of the discs to amount to 7 D., and on April 18 to 10 D. The case shows how important constant observation of the eyegrounds may be when the symptoms of brain tumor are present, and illustrates the danger of delaying decompression when the signs of increased intracranial pressure appear. It is often impossible to make the patient realize that the sight may be put in jeopardy within a few days, and he may neglect to visit the ophthalmologist, notwithstanding that every effort may have been made to convince him of the danger of this neglect.

Paton[4] has studied the records of 252 cases of brain tumor occurring at the National Hospital between the years 1899 and 1905. He finds that tumors of the deeper portions of the cerebral hemispheres and of the pons are more likely to occur without papilledema. In the subcortical cases the development of papilledema almost invariably corresponded with invasion of the cortex or with marked compression or invasion of the lateral ventricle. The development of papilledema in pontile tumors almost invariably implied the invasion of the cerebellum.

In the discussion of this paper Gunn[4] states that pontile tumors rarely cause papilledema because death occurs early.

The statements quoted from the remarks of Paton conform with the results of my own observations in great measure, but the explanation offered by Gunn for the infrequency of papilledema in cases of pontile tumor is inadequate. I have repeatedly seen tumors causing enormous enlargement of the pons before death occurred, and in Case 3 the tumor of the pons doubtless was enormous before papilledema occurred. The cerebellum was not implicated, and, notwithstanding Paton's statement, papilledema became intense. Likewise, in Case 2, the tumor occupied almost the whole of the occipital lobe, but caused no papilledema, even though it extended to the cortex. Rules are useful, but almost all have exceptions, and what is true of one series of cases is not true of all.

Some years ago Schmidt[5] advanced the view that an increase of the symptoms by lying on a certain side of the body was indicative of the side of the tumor. The sign has seemed to me exceedingly unreliable, and I have been observant of it since the first appearance of Schmidt's paper, but have never been able to obtain any satisfaction from it, and have come to entirely disregard it from a diagnostic point of view. Mrs. Y (Case 3), for example, was obliged to lie on the right side, and when she turned on the left side she complained of feeling sick and as if "everything were going from her." Turning the head to the left while lying down produced nausea. In this case the tumor implicated the entire pons.

In Case 5 the diagnosis had to be made between tumor beginning in the Gasserian ganglion and tumor of the pons. The patient had headache, vomiting, vertigo when headache was present, and diplopia. In my examination I found that he had considerable ataxia, slight nystagmus in looking far to either side, slight weakness of the left facial distribution, some impairment of hearing in the left ear, and marked paralysis of the left trigeminal nerve (atrophy of the temporal and masseter muscles with diminution but not complete loss of sensation in the distribution of this nerve) and paresis of the left side of the soft palate.

One might readily diagnose a tumor of the pons with these symptoms, but the examination also showed that the voluntary power of the upper and lower limbs on each side, as well as the tendon reflexes of these limbs, was normal. The ocular examination revealed beginning papilledema and paresis of the left external rectus. The deafness of the left ear was attributed to catarrh, as no signs of nerve deafness were detected.

Probably the most striking sign was the pronounced implication of the left trigeminal nerve, so intense as to cause a distinct flattening of the face over the position of the muscles supplied by this nerve; and this would seem to indicate a long-standing implication of the fifth nerve. A tumor of the Gasserian ganglion would explain this sign, as well as the escape of the motor tracts for the lower limbs. The left sixth nerve might easily be caught in its passage through the cranium. Pressure of the tumor on the pons—i. e., on the middle cerebellar peduncle—might explain the nystagmus on lateral movement and the ataxia. A tumor in this position might cause some weakness of the left facial nerve and beginning deafness. I am inclined to think that central deafness at first may be indistinguishable from deafness due to middle-ear trouble, and that we should be careful how we diagnose when deafness is in an early stage. The weakness of the left soft palate was difficult to explain by the supposition of a tumor beginning in the Gasserian ganglion and extending downward sufficiently to implicate the glossopharyngeal nerve, but no less difficult appeared the diagnosis of tumor within the substance of the pons sufficiently large to implicate the fifth, sixth, seventh, eighth, and possibly the ninth and tenth nerves, and yet cause no weakness of the limbs or change in the tendon reflexes. The diagnosis was extremely difficult and could not be made with certainty, and, in the hope that the tumor might be found in the region of the Gasserian ganglion, although pain in the face had not been severe, I requested Dr. Frazier to operate, but the tumor was not detected at the operation. It is indeed remarkable that a tumor so large as that found in this case could occupy a large portion of the pons and yet produce no weakness of the limbs or change of reflexes that could be detected in careful examination directed toward the finding of either of these signs. The explanation is that the growth was a glioma, and, as so often occurs in tumors of this variety, many nerve fibers passed *through the tumor without losing their axis cylinders*, even though they may have lost their medullary sheaths. Pain in the distribution of the fifth nerve would be more likely to occur in tumor of the Gasserian ganglion.

[5] Schmidt: Wien. klin. Wchnschr., 1898, No. 51.

The case shows clearly that the diagnosis between a tumor upon the pons and one within the pons, if the latter be a glioma, my be extremely difficult or even impossible. A case presenting the same difficulty I studied with Dr. W. A. Bliss in St. Louis somewhat over a year ago.

In my chapter on tumors of the brain, in the book edited by Dr. Posey and myself,[6] I give the symptoms that have been observed in tumors of the occipital lobe. Visual hallucinations are mentioned, and several references are given to cases in which these phenomena occurred. The hallucinations seem to occur in the blind fields, and this statement is also made by Oppenheim.[7] The appearance of homonymous lateral hemianopsia, followed by gradually developing hemiplegia and loss of sensation, all the symptoms being on the same side, is suggestive of tumor, especially if the hemianopsia be accompanied by visual hallucinations. The latter may be absent throughout the course of the disease; thus Claude and Rose[8] have recently reported two cases of tumor of the occipital lobe in which visual hallucinations were not observed. They assume that such hallucinations are caused by irritation of the calcarine cortex, and were absent in their cases because the tumors were in the white matter of the occipital lobe. This seems to be assuming too much, as we have sufficient evidence to show that a lesion need not be confined to, or even be located within, the calcarine cortex to produce visual hallucinations, and this statement is justified by Case 6. I have emphasized this fact also in my chapter referred to above. Claude and Rose refer to the fact that the hemianopsia in tumor of the occipital lobe is seldom complete from the beginning, but, after being partial for a time, may rapidly become complete, so as to suggest a thrombotic lesion. In one of their cases an examination made Jan. 9, 1907, revealed a left homonymous lateral quadrantanopsia. Another examination, made Feb. 24, 1907, showed that the hemianopsia had become complete.

All writers who refer to visual hallucinations in cases of brain tumor, so far as I have been able to study the literature on the subject, speak of the hallucinations as occurring on the side opposite to the tumor. This generally accepted opinion led me to a diagnosis of the wrong occipital lobe in a case seen with Dr. William H. Teller (Case 6). The patient stated positively that he had frequent attacks, in which wriggling bright lights, beginning always in the right field, gradually passed to the center of the field, and disappeared in the left field. These phenomena were accompanied by dimness of vision, beginning also in the right field and disappearing in the left field. Since optic neuritis had occurred he saw black objects looking like snakes, rosettes, and forms of leaves in front of the eyes; occasionally he saw the heads of persons. Believing from these phenomena that the tumor was probably on the side opposite the fields in which the hallucinations first appeared, and therefore in the left occipital lobe, I suggested to Dr. Teller that it would be well to expose the left occipital lobe. The tumor, however, was in the right occipital lobe. It would seem from this case that *visual hallucinations may occur in the field on the same* side as the tumor, or at least begin in this field. The patient was intelligent, his mind was active, and his statements regarding his visual phenomena were reliable.

The only important signs of tumor in this case were papilledema of high grade and visual hallucinations. Hemianopsia was not present, and the absence of this sign is explained by the examination after death, as the tumor does not appear to have implicated the visual fibers. It seems almost impossible to have made any other localization than that made in this case, unless we can judge from one case that visual subjective phenomena may occur in the field on the same side as the tumor.

Another case seen with Dr. J. T. Rugh more recently lends support to this view. A woman with signs of brain tumor saw flowers and "red, green and bright colors," and dogs, to her right, and on one occasion she saw bird-cages and an open trunk, but it is not certain where she saw these; the flowers and dogs she was sure she saw to the right. Spontaneous pain in the right parieto-occipital region and tenderness to percussion here, normal right patellar reflex and exaggerated left patellar reflex, and some impairment of ability to recognize objects with the left hand, indicated that the lesion was on the right side. The tumor was not found at operation, but the pressure of the right cerebral hemisphere through the opening was enormous.

Lewandowsky[9] refers to the amnesic color-blindness of Wildbrand. This seems to be a sensory aphasia confined to the names of colors. Patients presenting this sign are unable to name colors shown them and to pick out colors named to them. Lewandowsky is uncertain whether this symptom occurs in a pure form, and is inclined to think that the symptom-complex belongs to his dissociation of the color-sense. His patient had sensory aphasia, was word blind and word deaf, but after these symptoms had almost disappeared the peculiar color-symptoms were detected. He had homonymous right lateral hemianopsia. Like my patient referred to below, the man was not mind-blind. My patient had no difficulty in recognizing and avoiding objects. Lewandowsky's patient was unable to name the colors of objects shown to him or to find colors named to him. He could not name the color of an orange or a leaf (my patient could not name the color of blood or of snow). He also could not find the proper colors of objects from samples shown him, as my patient also could not. The disturbance evidently did not depend merely on a speech defect. His patient also did not observe anything peculiar in pictures colored unlike objects occurring in Nature. *He was able to match colors.*

[9] Lewandowsky: First Internat. Cong. Psychiat., Neurol., etc., Amsterdam, 1907; Monatsschr. f. Psychiat. u. Neurol., 1908, xxiii, 488.

Lewandowsky believed that a lesion had destroyed the color-center of the left hemisphere, but that the color-center of the right hemisphere was preserved. The association of the color-sense not only of the left center but also of the right center was through the left color center, and, this being destroyed, association of color with form was impossible. Whether the left occipital lobe is the more important in every person is not determined, but in all reported cases of cerebral disturbance of the color sense the left hemisphere has been affected.

It would seem that in this dissociation of the color-sense described by Lewandowsky[9] we have a new and important sign of lesion of the left occipital lobe. It is possible that it might occur without other sign of lesion of the occipital lobe, but it is probable that we shall always find hemiamblyopia, as in my case, or even hemianopsia.

A patient in the service of Dr. John H. Musser, whom I had the opportunity to examine, presented this symptom of color disturbance, which promises to be of value in diagnosing lesions of the left occipital lobe. It is not my intention to enter into a full description of the case in this place. He had right lateral homonymous hemiamblyopia, intense word-blindness, slight word-deafness, and some amnesic aphasia, i. e., he could not always find the word he desired in speaking. As there was a possibility of tumor, although the lesion was believed to be thrombosis, I recommended exposure of the left occipital lobe with the angular gyrus as a center, and softening of the occipital lobe was found by Dr. Frazier and the diagnosis confirmed by the examination of a small piece of excised tissue. An examination made by me before the operation gave the following results:

The patient could name most objects shown to him, such as a watch, knife, key, handkerchief, but sometimes made mistakes. When shown the picture of a dog colored deep blue or the picture of a donkey colored deep green he found nothing peculiar in these colors, and said when asked that he had often seen a dog or a donkey of the colors mentioned. He was entirely unable to give the name of any color shown him, and when the correct name of the color was mentioned among others he did not recognize it. He could match colors without the slightest hesitation. He was entirely unable to find a color mentioned to him when a variety of colors was placed before him. He was unable to name the color of any object shown to him, as that of a leaf. He answered, "I know what all that is, but I can not remember." When asked what a leaf was he said that he did not know.

A hasty examination would have led to the conclusion that the patient was color-blind, as he did not remember the color of any object, did not name the colors shown him, did not see any impropriety in the coloring of a dog blue or a donkey green, and yet the preservation of the color-sense was shown by his ability to match colors without the slightest hesitation. He had merely lost the ability to associate color with form; he recognized the form of most familiar objects and matched colors, but was entirely unable to put form and color together. He had what Lewandowsky has described as *Abspaltung des Farbensinnes,* which might be translated as dissociation of the color-sense.

It is usually difficult or impossible to form an opinion of the character of the tumor from the symptoms. As regards the possibility of this, Oppenheim[10] says:

> The symptoms are not essentially modified by the character of the growth, especially when the syphilitic process is left out of consideration. The same symptom-complex may be produced by glioma, sarcoma, solitary tubercle, and other tumors. The glioma sometimes is characterized by apoplectiform attacks, which may occur repeatedly and be associated with a rise of temperature. The vascularization may cause much variation in the intensity of the symptoms. The glioma has a slow growth, excepting the acute attacks caused by hemorrhage and swelling. Remissions are not uncommon.

Ludwig Bruns[11] speaks of the uncertainty in diagnosing the character of the tumor from the symptoms, but he thinks that very acute commencement of symptoms, possibly after slight trauma, in a person previously apparently entirely healthy, is suggestive of glioma. Rapid variation in the intensity of the symptoms and sudden increase in the symptoms are also common in glioma, but occur in other forms of tumor. The diagnosis between glioma and sarcoma especially is difficult.

There is still another way by which we may draw conclusions regarding the presence of glioma: The general symptoms of brain tumor, associated with the signs of a widespread lesion as of the greater part of the pons, with the escape of important fibers situated within the lesion, as those of the pyramidal tract, should be indicative of glioma. In no other form of tumor is the escape of fibers within the tumor so likely to occur. In two of the cases reported in this paper the justification for this view is clearly presented (Cases 3 and 5).

REPORTS OF CASES

Case 1.—*Patient.*—D. P. (Lab. No. 467) was referred to me Jan. 11, 1909, by Dr. S. W. Gadd. He had been well until six weeks previously. He denied venereal disease, and his wife had not had any miscarriages. A left hemiplegia had developed gradually, there had not been at any time a sudden loss of function, for example he was weaker at the time I saw him than he had been two weeks previously. He had not taken alcohol for twelve months, previous to this time he drank occasionally. He had not had headache, and gave no history of trauma. During the five days previous to his visit to me he had vomited almost every day. He had not had convulsions.

First General Examination.—The notes concerning his condition at my first examination are as follows: "Mentality is good, and he talks fluently. The sight has failed during the past two years. He has slight weakness in the lower left side of face, not in the upper part of face. The tongue is protruded in the median line. The left upper and lower limbs are weak, but he still has considerable power in these limbs. The biceps and triceps tendon reflexes are a little exaggerated on the left side. The patellar reflexes are prompt, and the left is distinctly exaggerated. Ankle clonus is present on the left side, but not on the right side. There is no hemianopsia.

---

[10] Oppenheim: Die Geschwülste des Gehirns, ed. 2, p. 221.

[11] Bruns, Ludwig: Die Geschwülste des Nervensystems, ed. 2, p. 260.

Sensations of touch and pain are less acute on the whole left side; in face, upper and lower limbs. He has marked tremor of the right hand. He drags the left foot when walking. He has no hemianopsia."

Second General Examination.—The change that occurred in this patient's condition between January 11 and February 6 was very great. An examination made by me on the latter date gave the following results: "The man is in stupor; he mutters constantly, and makes irrelevant remarks. Hiccough is pronounced. He lies with his head turned to the right and the neck is stiff. The palsy in the lower part of the left side of the face is distinct. The stupor prevents any careful testing of the power of the upper part of the face. It is impossible to get him to protrude the tongue beyond the lips, or to make him move the eyeballs on command. The reaction to light is present in each eye, but feeble. He moves the right upper limb freely. The left upper limb is completely paralyzed, is flaccid, and falls lifeless when elevated. The right upper limb is somewhat spastic. The biceps and triceps tendon reflexes are about normal on each side, although they may be a little prompter on the left side. He seems to feel pin-prick in the left hand. The left lower limb is completely paralyzed, and falls lifeless when elevated. The patellar reflex is about normal on each side. Ankle clonus is not obtained on either side, and the Achilles reflex is weak on the left side. The Babinski reflex is uncertain on each side."

Ocular Examination.—The notes dictated by Dr. de Schweinitz regarding the ocular condition are as follows: "Pupils dilate thoroughly with homatropin. Right disc shows no swelling or edema, outer half has atrophic pallor. No definite signs of previous neuritis. Central vessels are small. The right disc is similar to the left, but of better color. In both maculæ patches of retinochorioiditis."

The man's condition became gradually worse, and he died February 10, at 6 a. m., his temperature, which had been irregular while he was in the hospital, rising to 106 just before death. A tumor was found in the region of the right optic thalamus.

Autopsy.—When the ventricles of the brain were opened after death no excess of fluid was found within them. The right optic thalamus fluctuated as though it contained fluid, and when a horizontal section was made through the cerebral hemisphere a cyst was found in the region of the upper part of the right optic thalamus and inner capsule. Twelve c. c. of cloudy yellow fluid were collected from this cyst. The tumor caused considerable enlargement of the right side of the brain, as shown by a horizontal section through both hemispheres at the level of the upper part of the optic thalamus. At this level it measured 4 cm. from before backwards and transversely. The cyst occupied the entire center of the tumor, leaving a narrow wall of tumor tissue. The growth was well defined from the surrounding tissue to the naked eye, and did not have an infiltrative appearance, nor did it extend into the lateral ventricle, but was separated from it by about 2 cm. of what appeared to be brain tissue.

Histologic Examination.—Under the microscope the tumor had a papillomatous appearance. It was sharply defined from the brain tissue, but extended into it by numerous nests of cells. It was very vascular and many of the vessels were surrounded by a row of cylindrical or somewhat cuboidal cells, each having a nucleus at the end nearer the vessel, the cells resembling the lining cells of the ventricle. The vessels were limited by a row of endothelial cells and separated usually by a space from the surrounding row of columnar cells. The tumor contained much detritus and some fatty granular cells. It had the appearance of adenocarcinoma, and seemed primary.

A squamous-cell carcinoma was found in the esophagus, but it is questionable whether the tumor of the brain could be considered as a metastatic growth from the tumor of the esophagus, especially as it was of a different type of carcinoma, and was solitary in the brain. The necropsy was performed by Dr. Karsner.

A very similar tumor of the brain has been described recently by Kölpin.[12] It was papillomatous and was regarded as an adenocarcinoma. It resembled glandular tissue where the tumor processes were cut transversely. It was sharply defined from the surrounding nervous tissue, but caused no distortion of the tissue about it, so that the growth of the tumor was proportional to the destruction of the nervous tissue. Masses of detritus were found in the center of the tumor, whereas the center of the tumor in my case had become cystic and the tumor had caused enlargement of the hemisphere.

Primary epithelial growths of the brain, Kölpin states, are rare findings. They arise in the ependyma of the ventricles or the lining of the chorioid plexus and have a papillomatous formation. Kölpin refers to a number of reported cases. He believed that the largest of his tumors was the primary growth and that it originated in the ventricular wall, although such a connection could not be positively detected, any more than it could be in my case.

Case 2.—*Patient.*—M. Sher. (Lab. No. 448) was admitted to the service of Dr. Edward Martin, at the University Hospital, April 23, 1908. I report the case with his permission. The patient's age was 53. The history of his illness was obtained from his wife. He was said to have been kicked by a horse in the head during the summer of 1907, but was not disabled at the time. He had not been sick during the past twenty-eight years, and he had not been a drinking man. He had been complaining occasionally for some months of headache, and his wife had noticed drowsiness, which gradually increased until he stopped work nine weeks previously. At that time he complained of severe headache in the left parietal region and seemed confused. The headache was persistent. During the four weeks previous to admission he had been in bed and was stuporous most of the time, though occasionally rational for short periods. The right arm was said to have become paralyzed four days prior to admission, and the right leg about a week before admission. The paralysis of the lower limb had developed gradually. Further investigation made the duration of the stuporous condition as given doubtful, and it seemed probable that it may have begun only a few days before he entered the hospital. When he entered the hospital he was stuporous all the time.

Ocular Examination.—Dr. Shumway made the following report: "Pupils are equal and respond to light. There is much mucopurulent discharge, obscuring the cornea. He has bilateral incipient cataracts. Retinal veins are full, but not tortuous. There is no blurring of the nerve edges, no neuritis. The eyegrounds show no gross lesions."

General Examination.—An examination by me April 25 gave the following results: "Once when he was told to show his teeth he did so, and the nasolabial fold appeared to be as deep on one side as on the other. When the face is pricked with a pin on either side the corner of the mouth is drawn up, and there is no distinct evidence of facial palsy. He has a tendency to repeat in a whisper what is said to him. Pin-prick evidently causes pain in the face. Tactile sensation can not be tested anywhere because of the mental state. He partially understands what is said to him. The neck muscles are distinctly rigid. The right upper limb appears to be completely paralyzed; pricking with a pin in this limb causes some movement of the left upper limb, but none of the right upper limb, and the pricking is not correctly localized. The right upper limb seems to have impaired sensation. The biceps and triceps reflexes are about normal in the left upper limb, but somewhat exaggerated in the right upper limb. Testing with a feeding-cup seems to indicate that the man has right hemianopsia. The patellar reflex is much diminished on the left side and is normal on the right side. The Achilles-tendon reflex is prompt on each side. The right lower limb seems to be completely paralyzed. Pin-prick causes no movement of this limb, but probably causes some sensation of pain, as the man moves his left limbs as though he were in discomfort, and yet pain sensation appears to be diminished in the right lower limb. The Babinski reflex is not obtained on the right side, the toes not being moved in either direction; it is probably present, though somewhat uncertain on the left side." Leucocytes were 12,400.

---

[12] Kölpin: Arch. f. Psychiat., xlv, No. 2, p. 595.

Course of Disease.—The important features of this case were a gradually developing right hemiplegia, probably right hypalgesia, right hemianopsia, rigidity of the neck, a temperature that varied from 100 to 101, and the absence of ocular changes. Dr. Martin performed an exploratory operation April 28. Nothing abnormal was found. The right upper limb moved in response to electrical stimulation in the motor area. The man died April 30.

Autopsy.—A tumor occupied the greater part of the lower half of the left occipital lobe. It extended almost to the inner capsule and had the appearance of an angioglioma.

Case 3.—*Patient.*—Mrs. Y., aged 45 (Lab. No. 449), was seen by me March 23, 1908, in consultation with Dr. J. Thorington, by whose courtesy I report the case. Dr. Thorington sent the patient to me with the diagnosis of brain tumor, a diagnosis that seemed to me correct after an examination. My notes as taken from my case book are as follows:

General Examination.—"Mrs. Y. . . . has been complaining of vertigo about one year. When in bed she is obliged to lie on the right side; when she turns on the left side she feels 'sick and as though everything were going from her.' Her weight has decreased from 155 pounds to 121 pounds. Turning of the head to the left while lying down produces nausea. She vomits often in the morning. She has had pain in the muscles of the neck, and often a throbbing sensation in the frontal and occipital regions, especially when bending over. She is hungry all the time, and has a 'most vigorous appetite.' The menses are regular. The throbbing in the back of the neck is very severe and extends down the neck to the shoulders. She can not read unless the print is very large. She complains of kicking and jerking in her lower limbs, and can not lie down in the daytime because of this, and is kept awake at night by it. All symptoms began a little more than a year ago. The pain in the head is slight when she is sitting very still. She chokes when eating and swallowing, but if her attention is diverted she has no difficulty of this kind. She has three children, all healthy, and has not had any miscarriages. She complains of numbness all over both sides of the face, the numbness began on the left side of the face. The roof of the mouth also is numb. She has not had any pain in the face. She staggers on the street like a drunken person. Her behavior at times appears childish. The right pupil is a little larger than the left and both react to light, accommodation and convergence. She has marked nystagmus in looking to the right, and less in looking to the left, none in looking upward or downward. The nasolabial fold is slightly less distinct on the right side, when the face is at rest, but in showing the teeth or in drawing up either corner of the mouth separately, there is weakness of the left side in the whole distribution of the facial nerve. The right masseter is stronger than the left. Touch and pain sensations are normal in each side of the face. She has marked diminution of the conjunctival and corneal reflexes on the left side. She hears the voice and watch well on each side. The tongue when protruded sometimes deviates to the right, sometimes to the left, or is in the median line. The soft palate moves normally. The finger-to-nose test shows very little if any ataxia. The grasp of each hand is good. There is no impairment of voluntary movements in either upper limb. The biceps and triceps reflexes are exaggerated in each upper limb. Touch and pain sensations are normal in the hands and feet. Voluntary power is normal in the lower limbs. The patellar reflex is exaggerated on each side. The Achilles reflex is a little exaggerated on each side and about equally. There seems to be a slight Babinski reflex on each side, but it is uncertain. She has no ankle clonus. She sways very distinctly with the eyes open, and more so with the eyes closed, and during my examination she falls frequently toward the right. The gait is ataxic, and more so with the eyes closed." She presented on one occasion adiadokokinesis in the right hand.

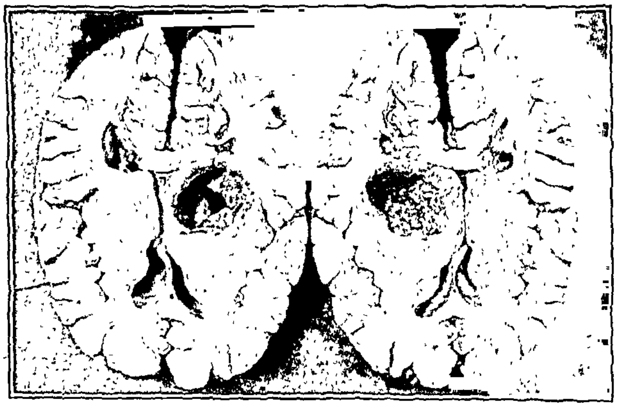

Fig. 1.—Case 1. Adenocarcinoma of the right optic thalamus and adjoining region.

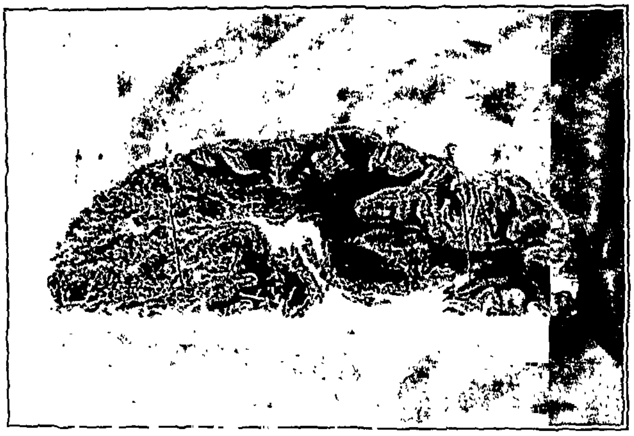

Fig. 2.—Case 2. Glioma of the left occipital lobe.

Ocular Examinations.—A letter from Dr. J. Thorington, dated March 21, 1908, stated: "The ophthalmoscope does not reveal any pathologic changes at this time. The eyegrounds are apparently normal and the discs are not elevated. Vision in each eye is normal, and the refraction + 1.25 sphere, together with presbyopia." On April 7, 1908, Dr. Thorington wrote: "Yesterday and today I noticed that the nasal side of each disc has commenced to be elevated and indistinct in outline; the retinal veins are enlarging and becoming tortuous." Dr. Thorington reported that the swelling of the discs reached 7 D. on April 13 and 10 D. on April 18. Operation was considered, but as nothing more than palliation could be offered the relatives declined to have an operation. Death occurred May 4, 1908.

Autopsy.—A glioma occupied the whole of the pons. The left optic thalamus and adjacent region were much larger than the corresponding area of the right hemisphere. The lateral ventricles, especially the left, were distended. A microscopic section from the tumor of the pons stained by the Weigert method, showed few nerve fibers. The anterior pyramids were well stained by the same method.

Case 4.—*Patient.*—D. T. (Lab. No. 422) was admitted to the Philadelphia General Hospital July 12, 1907.

History.—The patient had used alcohol, absinthe and tobacco to excess, but denied having contracted any venereal disease. He had been a clerk for twenty-five years. His symptoms began about ten months before his admission. He suddenly lost consciousness about thirty minutes, and six days later he had a similar attack which lasted three days. He could not describe these attacks more fully, but stated that he had had only two. He had had constant headache since the beginning of his symptoms, and it had varied in intensity, and was confined to the frontal region. He had been gradually losing power in his right upper and lower limbs, and his general vigor was impaired; he had lost his appetite and was unable to use his mental faculties as well as formerly.

First Examination.—His gait on admission was slightly hemiplegic, and he dragged the right toes. Sway was increased by closing the eyes. The pupils were unequal, the left being slightly larger. Response to light and convergence was preserved. There appeared to be some weakness of the right side of the face in showing the teeth. Both upper limbs were weak, the right more so. There was slight tremor in both hands. The biceps and triceps reflexes were prompt on both sides. The right patellar reflex was slightly exaggerated, and ankle clonus was present on the right side. The speech was slurring, and test words were pronounced with some difficulty. His memory was poor, and he was easily confused. Soon after he entered the hospital he acted queerly, was dazed, attempted to disrobe in public, and did not know how to put on his clothing.

Second Examination.—Dr. Weisenburg, examining the man Sept. 18, 1907, noted that the right lower limb was contracted, and that the right upper limb was spastic. Right partial hemianopsia, and right hemihypesthesia were present.

Third Examination.—The man was examined by me Jan. 1, 1908. He was very stuporous, talked voluntarily, but irrationally. He heard when spoken to, but did not reply correctly. He had rigidity of the neck. The upper limbs were very rigid, especially the left. The upper limbs were adducted on the chest, with the forearms flexed on the arms, the left more than the right. The left palpebral fissure was larger than the right. The nasolabial fold was smoothed out on the left side. The biceps and triceps reflexes were restrained by the spasticity of the limbs. Although there was *no distinct conjugate deviation*, he had a tendency to turn his head to the right, but the eyeballs did not deviate. The legs were kept flexed on the thighs, the right as much as the left. They could be extended to an obtuse angle with the thighs. The spasticity was great and equal in the two lower limbs. Ankle clonus was persistent on both sides. Involuntary twitching occurred in the lower limbs.

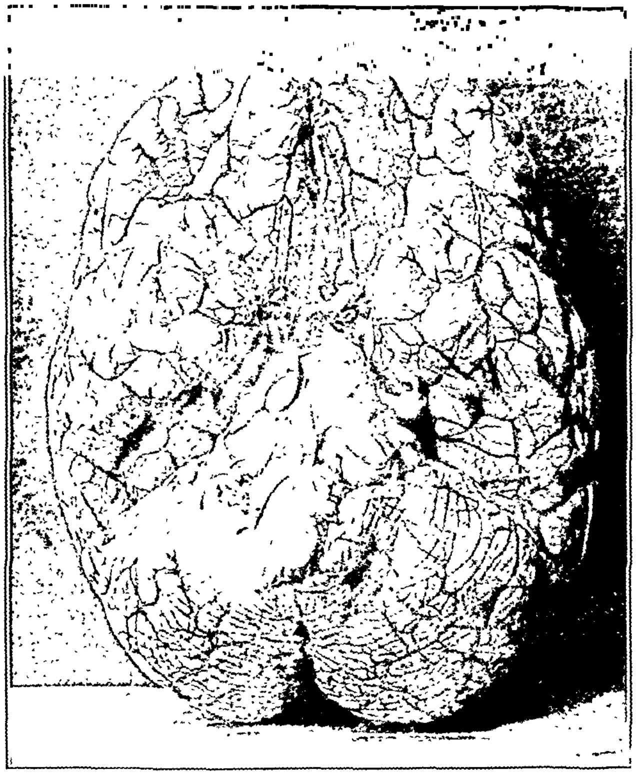

Fig. 3.—Case 3. Glioma occupying the entire pons.

Course of Disease.—At the time he came under my observation the symptom-complex was bilateral, and as much pronounced on one side as on the other. The history stated that the hemiplegia had developed gradually, but the left side seems soon to have become affected. Unfortunately no examination of the eyes was made; at least no record was made of any examination. It probably would not have revealed papilledema. The condition became gradually worse and the man died Feb. 2, 1908.

Autopsy.—The right optic thalamus was much larger than the left, and the enlargement was uniform. The left was concave slightly on its inner side to accommodate the enlarged right optic thalamus. The tissue posterior to the right optic thalamus had distinctly the appearance of a glioma, and the tumor was fairly well defined, especially where it projected as a rounded mass into the posterior horn of the lateral ventricle. No limitation could be placed to the anterior border of the tumor.

Case 5.—*Patient.*—R. F. (Lab. No. 452) came into the University Hospital, July 23, 1908, referred by Dr. Rice. His age was 25. The notes taken at that time are as follows:

History.—"About nine months ago he began to have trouble with his eyes, his vision appearing indistinct and blurred. The disturbance has increased and for three or four months he has been seing double. The eyes ache a great deal. Shortly after the beginning of the visual disturbance he noticed that his lower limbs were unsteady, and the difficulty in walking has increased. Walking in the dark is especially difficult. During the winter he began to have severe headaches. At first these were daily, but they have become less frequent, until now he has them every three or four days. The severity of the headache has increased. The headache usually begins in the morning and lasts most of the day. He frequently vomits when he has a headache. The vomiting is not projectile, and he is nauseated when he vomits. Two or three months ago his speech became thick. He is dizzy when he has a headache if he attempts to move about. He is becoming a little deaf. He has never had convulsions, but a few times he has had a shaking of the left forearm. He has had some difficulty in passing the urine, but no disturbances of the bowels. He has not had any numbness. He has lost flesh. He denies venereal disease."

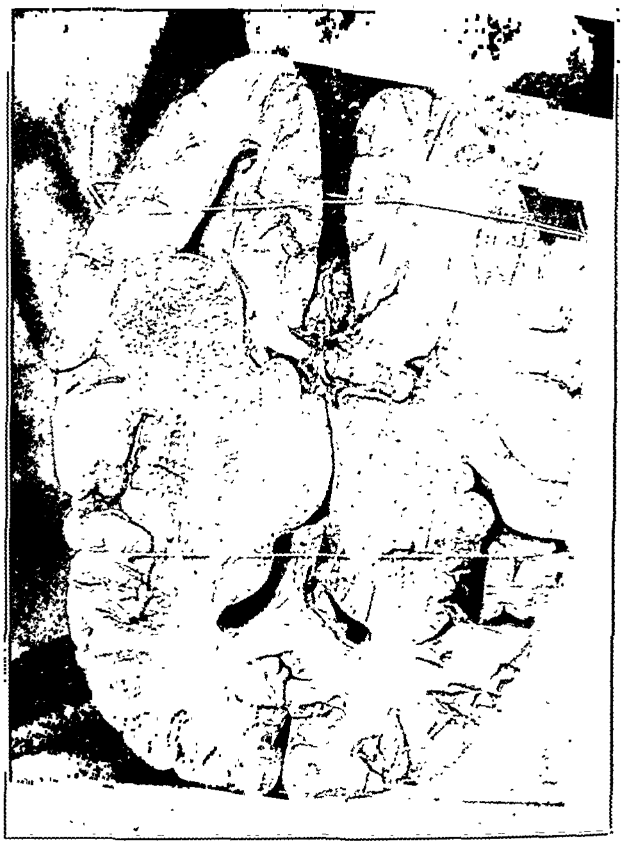

Fig. 4—Case 4 Glioma in the region posterior to the right optic thalamus.

Examination.—This, made by me July 27, 1908, gave the following results: "In walking he staggers with the eyes open or closed, and the tendency seems to be to go more to the left. His face has a smoothed-out appearance, like the face in paresis. He wrinkles his forehead well and about equally on the two sides, although possibly there may be a little weakness in the upper distribution of the seventh nerve of the left side. The left eyelids can be opened more easily when closed in resisting passive motion; the left corner of the mouth is a little weakened both in showing the teeth and in drawing up the corners of the mouth separately. The tongue is protruded slightly toward the right. He has slight lateral nystagmus in looking to the extreme right or left. The hearing of the voice and of the watch is distinctly impaired in the left ear, but the hearing may be imperfect also in the right ear. The left side of the face in the region of the temporal and masseter muscles is flattened as though these muscles were much atrophied. In biting there is no contraction in either the left temporal or left masseter muscle, and the man says that his teeth do not touch on the left side. The left soft palate is paretic. Tactile and pain sensations are diminished in the distribution of the left fifth nerve, but not lost. The left conjunctiva and cornea are almost anesthetic. The grasp of the right hand is about equal to that of the left, and is fair. The biceps and triceps reflexes are about equal, possibly a little prompter on the right side. Tactile and pain sensations are probably a little diminished in the left hand, but this is questionable. The pateller reflexes are about normal. He has a slight Romberg sign. The Achilles-tendon reflex is prompt on each side, and about equal on the two sides. The voluntary power in the lower limbs is about normal." The patient stated at this examination that he had had a "touch-like" sensation in the left side of the face, but only when he touched the face, and he had never had any pain in the face. On another occasion it was stated that the right pupil was slightly larger than the left, both eyes reacted to light and in accommodation, but the response seemed to be slower in the right eye. In testing taste there seemed to be no impairment to sweet or bitter substances. The recognition of objects in the hands and the sense of position were intact. A report from the eye dispensary stated that there was beginning papillitis, more advanced in the right eye. The fields were concentrically contracted. The left external rectus was paretic. The reaction of the left seventh nerve as tested by Dr. McConnell was normal to the galvanic current. The left fifth showed a quantitative but no qualitative change. The left side of the larynx was found to move less freely than the right side. The deafness of the left ear was attributed to catarrh, and Dr. Butler, in Dr. Randall's clinic, was unable to find any signs of nerve deafness.

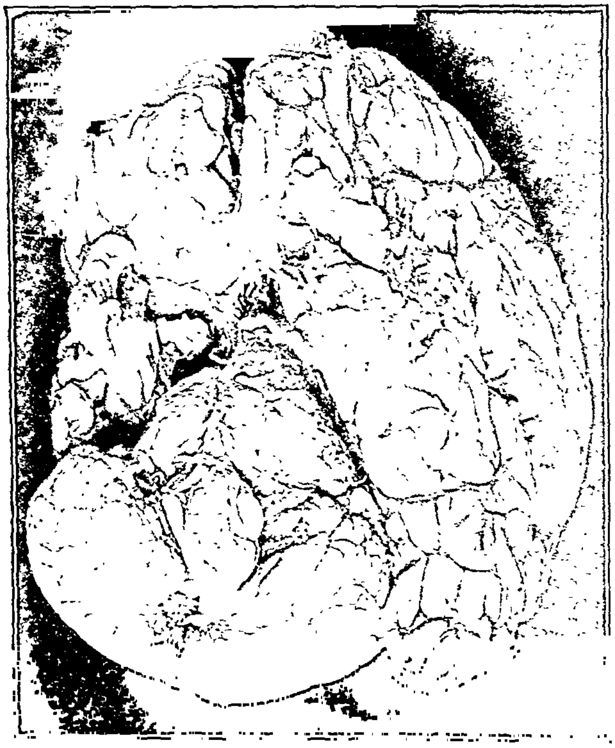

Fig. 5.—Case 5. Glioma of the left half of the pons and left half of the medulla oblongata.

An operation was performed by Dr. Frazier in the hope that a tumor in the region of the Gasserian ganglion might be found, although such a finding might be doubtful. Decomposition might be of benefit, and save the sight. It was the only chance offered to the patient for relief, and proved to be ineffectual.

Autopsy.—A tumor occupied the entire left half of the pons, the right half appearing normal to the naked eye. It involved the entire left half of the medulla oblongata, causing much enlargement corresponding to the great increase in size of the left half of the pons. The right half of the medulla oblongata appeared to be normal to the naked eye. The left cerebral peduncle was not enlarged. No tumor was found in the left Gasserian ganglion, and this ganglion seemed to be in good condition. A microscopic section of the medulla oblongata showed that the tumor invaded the right side. Nerve fibers were found in all parts of the section, but the tissue was rarefied as though the nerve fibers were pushed apart by the infiltrating glioma.

CASE 6.—*Patient.*—G. D. (Lab. No. 450), aged 50, was a patient of Dr. W. H. Teller, with whom I saw the case in consultation and by whose courtesy I report it. Syphilis was denied. The notes obtained March 18, 1908, are as follows:

History.—"Fifteen months previously while sitting on the porch he suddenly became aware of some visual disturbance, but was not unconscious, he could not see plainly, could not hold a pencil properly, could not say the words he desired to say; he was able to walk, he vomited, had severe pain over the entire head, slept badly the following night, but the next day he returned to work. He has not had any vomiting since that time. During the past three weeks he has seen objects before his eyes resembling snakes."

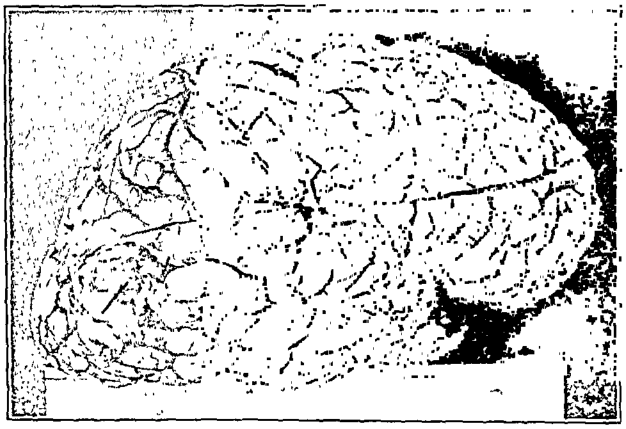

Fig. 6.—Case 6 Glioma of the right occipital lobe, indicated by a line.

First General Examination.—"Pupils are equal; the reaction to light and in convergence is preserved; there is no nystagmus; no disturbance of tactile or pain sensation in the face. The patient can wrinkle the forehead, close the eyelids and draw up the corners of the mouth well on each side; the tongue is protruded in the median line; he hears the voice distinctly in each ear. The finger-to-nose test shows no incoordination; the power is good in both upper extremities, as is also sensation for touch and pain. The patient recognizes objects in either hand with the eyes closed, and has no impairment of the sense of position. The triceps and biceps reflexes are normal. The station and gait are normal with eyes open or closed. The patellar tendon reflexes are prompter than normal. The Achilles-tendon reflexes are prompt. Babinski's sign is not obtained. Sensation in the lower limbs is normal."

Second General Examination.—Notes taken on April 23, 1908, are as follows: "The right external rectus is weak.

There is no hemianopsia, no anesthesia of the conjunctiva, no weakness in the facial distribution of either side. Touch and pain sensations are normal in the face. Masseter and temporal muscles contract well on each side. Tongue is normal. Hearing of voice and watch is good in each ear. There is no area of tenderness of the scalp, no stiffness of the neck. The power of each upper limb is good. A slight Romberg sign is obtained at this examination. He has had frequent attacks in which wriggling bright lights, beginning always in the right field, gradually passed to the center of the field, and disappeared in the left half of the field; these attacks were with dimness of vision, beginning also in the right field and disappearing in the left field. Since he has had optic neuritis he has seen black objects like snakes, rosettes, and forms of leaves in front of the eyes, and sometimes he sees the heads of persons." In other respects the examination gave much the same results as obtained at the previous examination.

Ocular Examination.—Iridic reflex to light is slow, prompt in convergence. There is limitation in outward excursion in both eyes, especially to the right. No limitation in upward movement. Pupils: O. D. 2½ mm. O. S. 2¾ mm. Vision O. D. 10/20, O. S. 10/40. Marked papilledema, periphery 2D., center 7D. No hemianopsia. Fields are greatly contracted.

Operation.—Dr. Teller operated, as we hoped to find a tumor in the left occipital lobe, or at least produce a decompression that would benefit the patient. No tumor was found at the operation.

Autopsy.—A tumor measuring 3 cm. in length and 2 cm. from above downward was found in the lower part of the right occipital lobe. Microscopically it had the appearance of a glioma.

I am indebted to Dr. Alfred Reginald Allen for the photographs.

4409 Pine Street.

EXTENSIVE GLIOMATOUS TUMOR INVOLVING THE CEREBELLUM AND THE POSTERIOR PORTIONS OF THE MEDULLA, PONS AND CEREBRAL PEDUNCLE AND THE POSTERIOR LIMB OF ONE INTERNAL CAPSULE*

T. H. WEISENBURG, M.D.
Professor of Neuropathology and Associate Professor of Neurology, Medico-Chirurgical College; Neurologist to the Philadelphia General Hospital
PHILADELPHIA

Gliomatous tumors growing in the cerebellum are usually confined to it and only rarely do they extend into the adjoining parts. The following case is reported by itself because of the extraordinary growth of the tumor, which involved practically all parts of the cerebellum, but especially the inferior vermis, in an irregular manner all of the cerebellar peduncles, the posterior portions of the medulla oblongata, pons and cerebral peduncle, to a limited extent the posterior part of the optic thalamus and the posterior limb of the left internal capsule. The duration of the symptoms was about two years. The patient was under constant observation and the progress of the case was carefully observed, and some interesting observations were made in the progress of t[illegible], the tumor evidently involving the [illegible]d then growing into the cerebral peduncle and the medulla and then gradually implicating the posterior part of the pons. The growth was not properly diagnosed, but it was thought that there was a cerebellar tumor and an operation was performed over the right hemisphere. A part of it was removed for microscopic study. Definite cerebellar symptoms followed this removal.

REPORT OF THE CASE

Patient.—R., painter, aged 46. His family history was unimportant with the exception that both his father and mother died of Bright's disease. The patient had the usual diseases of childhood. He used tobacco moderately and alcohol to excess. He was a married man and had four living sons. There was no history of syphilis.

History.—The patient had been complaining for two years, his first symptom being headache, which was especially centered over the right parietal and occipital bones and back of the head. He was, however, able to work for a year, that is, until March, 1907, and then irregularly for about four months, ceasing then entirely. From this time until his death, which occurred in May, 1908, or about one year after the greater intensity of symptoms, he was under observation either in the dispensary or hospital. The headache was constant and of a dull character, being very great at times, increased by movement and not made better on lying down. A few months after the onset of the intense headaches, he began to be dizzy, describing the sensation as if he were rotating around the object at which he was looking. This dizziness became so intense that from the first he was compelled to have assistance in going up and down stairs and in walking, his gait being like that of a drunken person. Soon after this he began to be occasionally nauseated in the morning, this being accompanied by vomiting, later becoming more marked. In a short time he began to complain of general weakness, insomnia and of nervousness, and then noticed that he had some difficulty in talking, which consisted in an increasing thickness and slurring in his enunciation, being worse at times.

Anteoperative Examinations.—When he first came under observation at the dispensary he complained only of the general symptoms of headache, nausea, vomiting and dizziness with general nervousness, and walked like a drunken person. The indistinctness and slurring in his speech soon developed and he complained of weakness in his vision, especially on the right side, and then began to see double, one object being above the other. At the same time there was a drooping of the right upper lid. Examination discovered only a general increase of the reflexes and weakness in looking to the right and no incoordination. There was at first no choked disc, but subsequent examinations made by L. Webster Fox demonstrated an increasing optic neuritis which was equally marked in both eyes, the height of the swelling reaching 7 diopters. The patient was then admitted to the Medico-Chirurgical Hospital under the care of Charles S. Potts. Examination demonstrated a distinct drunken, ataxic gait, the patient staggering more to the right. Station was also uncertain. The power in the upper and lower limbs seemed to be normal, the grip measuring by the dynamometer 90 in both hands. The tendon reflexes in the upper limbs were normal; in the lower slightly increased. There was no ankle clonus or Babinski on either side. Sensation was not disturbed. The finger-to-nose and heel-to-knee tests showed some ataxia, especially on the right side. There was no weakness of the muscles of the back. The cranial nerves were normal with the exception that there was some diminution of hearing, especially on the left side, and there was drooping of the right upper lid, with weakness in the right sixth and inferior oblique. The pupils were normal and there was no disturbance in their reactions. There was nystagmus on looking to the left and upward. Speech was thick and indistinct.

Operation.—A decompressive operation was performed over the right cerebellar area. The right cerebellar lobe was cut and tissue removed for microscopic examination, but nothing was found. The patient made an uninterrupted surgical recovery; his optic neuritis gradually subsided; although at first there were some hemorrhages, his headache, dizziness and nausea became less and slightly improved.

Postoperative Examinations.—Examination made by me about three weeks after the operation demonstrated that the patient's headache subsided at first but soon became more marked and about equally so on both sides of the head in the posterior portion. The nausea and vomiting were less after the operation. The dizziness subsided for the first three weeks and then became as marked as before. This was not present when the patient was in a recumbent position or when sitting, but when he suddenly turned his head to the right he had a sensation of swimming or lightness of the head which was not of a definite character. Turning the eyes in any direction also produced the dizziness. When he stood up the dizziness. especially of self, was extreme, and he also had a sensation as if objects in front of him were swimming. A more definite description of the dizziness could not be obtained.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

* From the Laboratory of Neuropathology, Medico-Chirurgical College.

The pupils were larger than normal, irregular in their outline, and their reactions both to light and to distance were sluggish. He always saw double, objects being one above the other, and he generally kept his left eye closed so as to avoid the diplopia. Nystagmus was present very slightly on looking straight ahead, but was mostly marked in looking to the right and to a less extent to the left and then upward and downward. Convergence was normally performed in looking downward and in the median line, but in looking straight ahead and upward not so well, but the attempt at convergence was not lost. There was a weakness of the right external rectus and right inferior oblique.

The patient could wrinkle his brow well on both sides. the folds being equally marked, but the right brow was distinctly weak. There was a marked drooping of the right lower eyelid and corner of the mouth, and the right orbicularis palpebrarum was weak. The right masseters and temporals did not contract as well as the left and when the jaw was opened it deviated to the right. Sensation for touch and pain over the distribution of the right fifth nerve was diminished. Smell was not altered and taste could not be tested. Hearing was diminished on both sides. Throat examination demonstrated sluggish movements of the soft palate and some weakness of the vocal cords on both sides. His speech was thick, indistinct and difficult to understand.

At first the patient had no paralysis, but when examined by me, he had a distinct weakness in the right upper and lower limb, this consisting in a diminished grip and resistance. The left limbs seemed normal in power. The tendon reflexes of both the upper and lower limbs were prompt and equally so. There was no ankle clonus or Babinski on either side, plantar irritation causing no movement of the large toes. The patient stated that he could feel touch and pain better on the left side of the body than on the right. This was also true for bone sensation.

The head was held in the median line and the protrusion of the hernia in the right cerebellar area was becoming more marked. When the patient sat up in bed the incoordination of the body could be easily noticed; he swayed in any direction, but especially to the right. He could not stand up himself, and when not supported he would fall, especially to the right. He could not walk alone, but with aid he had a drunken, ataxic gait, more marked to the right side.

There was distinct hemiasynergia and ataxia in the right upper and lower limbs, this not being influenced by closure of the eyes. There was very little ataxia in the left upper and lower limbs. There was no disturbance of the senses of position, movement, localization or pressure.

Later History.—From this time on until his death, May 5, 1908, about six months after the operation, the patient was chair-ridden. He gradually became more stupid mentally and it was with difficulty that he could be made to understand, owing partially to his stupidity and then again to the fact that his hearing became very bad, being worse on the left side. When sitting up in his chair he would have to be supported on all sides, otherwise he would fall in a heap. He could not voluntarily sit up and if left free for a moment his body would immediately fall. He had a habit of sitting with his head bent to the right, the chin near his shoulder, the whole right side of the body drooping. His headache became less, but his dizziness grew more marked, and while at first this was not present when lying quietly, toward the latter end of his life, even when in this position with his eyes closed he had a sensation of self moving to and fro. He preferred to lie on his left side because he said this made him feel somewhat easier. The nausea and vomiting subsided.

Gradually there developed a prominence of the right eyeball. The patient would constantly keep his left eye shut, so as to avoid seeing double, and when he opened his eye there was a constant to-and-fro jerking of his eyeballs. His pupils became very large and their reactions both to light and movement were ultimately lost. It was with difficulty toward the last that he could be prevailed on to move his eyeballs or perform any movement. The weakness in the distribution of the right seventh nerve became more marked, especially in the lower part, and the right fifth nerve was involved both in its motor and sensory portion. The tongue could not be protruded more than beyond the lips; its movements were weak and it deviated to the right. The patient's speech became increasingly thick and indistinct. His eating became impaired because it was difficult for him to chew and he could not swallow readily, choking quite frequently. During the two months before his death there was constantly dribbling of saliva and his speech became unintelligible.

The weakness in his right upper and lower limbs became more marked and toward the end there was also some weakness in the left side, especially of the lower limb. The ataxia became gradually more distinct and the asynergic movements were earlier and more quickly demonstrated in the right limbs. There was also ataxia in the left limbs. It was especially noticeable that as long as the mentality was fairly good the tonicity in the lower limbs was about normal, but with the decrease of his mental power the ataxia became more marked and there was present a considerable lack of tone. Toward the end he voided urine involuntarily.

Observations were made on his respiration and pulse for about a month before his death, but no changes were noticed.

Macroscopic Postmortem Examination.—The brain was removed the following day. The right lateral lobe of the cerebellum was soft, this being the point of the operation. From gross examination before cutting, no enlargement was found of the peduncles, pons or cerebellum.

Microscopic Examination.—Sections were made of the cerebellum, medulla, pons, cerebral peduncles, of different portions of the brain and the spinal cord. An infiltrating gliomatous tumor was found, this implicating both lateral lobes of the cerebellum. especialy the left, and practically all parts of the vermis. The growth involved all the cerebellar peduncles in an irreguar manner, the posterior portion of the medulla almost as low down as the pyramidal decussation, the posterior part of the pons and cerebral peduncles, especially around the aqueduct of Sylvius, extending toward the cerebrum into the optic thalamus and involving the extreme posterior portion of the posterior limb of the internal capsule on the left side.

The growth was rich in cells; some nuclei were larger than others, being round, oval or spindle-shaped. They stained darkly and were granular. By the ordinary acid stains little intercellular substances could be seen where the cells were dense. but in other parts fibers could be made out, especially on the border of the growth. In parts, especially around the aqueduct of Sylvius, the vermis and the left lateral cerebellum, the cells were very dense and packed tightly together. There was no definite border to the growth, as tumor cells could be detected considerable distance away from the main mass. The vessels within the growth were thickened and had undergone in places hyaline degeneration.

Cerebellum: The size of the cerebellum was not increased. In practically all portions of the vermis, but especially in the inferior lobe, the cellular infiltration was intense. The left lateral lobe was infiltrated more than the right and infiltration was greater in the parts around the intrinsic nuclei and became less as the cortex was approached, but tumor cells could be seen in all portions.

Medulla: Sections of the medulla showed a broadening of the anteroposterior diameter. There was no degeneration of the motor fibers on either side. The growth involved the parts around the fourth ventricle. On the right it was considerably larger and infiltrated the nucleus cuneatus and gracilis and partially the restiform body. It implicated also the nuclei of the eighth, ninth, tenth and twelfth nerves and to some extent the nucleus ambiguus. The nerve cells, however, of these nuclei were not altogether destroyed, as here and there cells could be seen. The intramedullary portions of the twelfth, ninth and tenth, and eighth nerves were not degenerated, although tumor cells infiltrated parts of the fibers. On the left side, the infiltration was less, but here also the twelfth, ninth and tenth, and eighth nerves were partially involved, as were also the nucleus cuneatus and gracilis.

Pons: Sections made of all parts showed a broadening of the anteroposterior diameter, this becoming greater as the upper part was approached, the greatest broadening adjoining the cerebral peduncles. The growth was centered around and especially in front of the aqueduct of Sylvius, distorting it out of shape. Both sides were equally involved. The nuclei of the fifth nerves on both sides were implicated, especially the right. The nuclei of the sixth and seventh nerves were also involved, although all of the cells were not destroyed. The intramedullary portions of the fifth, sixth and seventh nerves were infiltrated in parts with tumor cells, but were not degenerated. Tumor cells could be found in the median fillet and to some extent in the anterior motor fibers. The posterior corpora quadrigemini, the superior cerebellar peduncles and the nuclei of the fourth nerves were almost totally replaced by tumor cells.

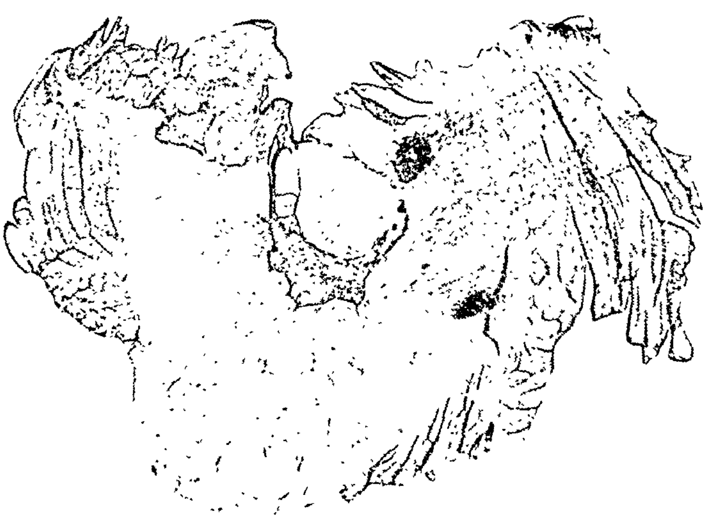

Fig. 1.—Section (actual size) cut through pons, middle cerebral peduncles and cerebellum. At the left, the site of the cerebellar operation can be seen. The tumor involves both cerebellar lobes, the left more so, all of the vermis and the posterior part of the pons. The left middle cerebellar peduncle is more involved than the right.

Cerebral Peduncles: There was no degeneration in the foot of the cerebral peduncles. The growth in this area involved the parts around the aqueduct of Sylvius, partially destroying the nuclei of the third nerves and the commissural fibers between them. The posterior part of the intramedullary fibers of both third nerves were implicated in the tumor. Both anterior and posterior corpora quadrigemina were involved, as were also the red nuclei, this being especially true on the right. Tumor cells could be found in practically all parts of the section. The antero-posterior diameter of the peduncle was increased.

Optic Thalamus and Internal Capsule: Some tumor cells could be seen in the posterior part of the thalamus and the growth involved the posterior portion of the internal capsule on the left side.

Cranial Nerves: Sections of the cranial nerves, with the exception of the first, showed some degeneration of the fibers. The right third and fifth nerves were more involved than the left, but in the other cranial nerves the degeneration was equal.

Spinal Cord: Sections were taken from the cervical, thoracic and lumbar cord and showed no degeneration. The nerve cells were normal and the anterior and posterior roots were intact and showed no degeneration.

Evidently the first symptoms observed were those referred to the cerebellum, such as headache, which was soon followed by nausea, vomiting, and a cerebellar gait in which the staggering was more to the right; then dizziness which was first described as if the patient were revolving around the object at which he was looking. He then began to have some difficulty in talking and in swallowing, and about the same time vision became impaired, although repeated ophthalmoscopic examinations did not demonstrate any choked disc, and it was not until about a year after the beginning of the headache that the neuritis made its appearance, rising then to 7 diopters. About the same time he began to see double, seeing one object above the other, and had drooping of the right upper lid. Examination demonstrated very little ataxia of the right upper and lower limbs, although the ataxia in walking was extreme. The patient also had a diminution of hearing on the right side. Because of the pressure symptoms, the cerebellar gait, more to the right, weakness of the right third nerve and the diminution of hearing on the left side, with difficulty in eating and talking, it was thought that he had possibly a cerebellar tumor, but the diagnosis was not clear because of the multiple cranial involvement on both sides.

An operation was performed over the right cerebellar hemisphere in which part of the right cerebellar hemisphere was removed and a whole group of symptoms developed directly after the surgical recovery. While before the operation there was not much ataxia and weakness in the right upper and lower limbs, this was marked afterward, and from then on until the patient's death, about five months later, the weakness progressed and the ataxia not only involved the right upper and lower limbs, but to some extent the left limbs. It was also noticeable that while before the operation there was no ataxia of the trunk muscles and apparently no weakness, afterward the patient could not sit up, but fell immediately in a heap and especially to the right. The reflexes were unaltered. For a short time he was able to walk, but his gait was distinctly ataxic and he staggered much more to the right. Alternate flexion and extension and other movements of the right upper and lower limbs were decidedly *more incoordinate directly after the operation.*

It is interesting to note that while clinically the preponderant cerebellar symptoms were on the right side, pathologically the left cerebellar involvement was greater, and that the vermis was more involved than either lateral lobe. It is probable, then, that the greater right cerebellar symptoms can be ascribed to the direct injury to the right lateral hemisphere at the time of the operation.

This is an interesting experiment on a human being and shows that the right cerebellar lobe controls coordination chiefly of the right limbs and also to some extent has an influence on muscular power. This has been demonstrated by other observers and has also been reported by me in a previous paper.[1] It is, however, interesting to note that while the ataxia and weakness developed in the right limbs, there was very little atonia and this did not make its appearance until the patient became stupid mentally.

The headache, nausea, vomiting and choked disc diminished gradually after the operation, but the dizziness became much more intense. While at first he felt as if he were revolving around an object, he now developed a constant dizziness which finally prevented him from sitting up. At first he only had this when moving his head or eyes, but later it was also present when lying quietly. He described the dizziness as a sensation of swaying or swimming either of self or of objects.

---

[1] Weisenburg, T. H.: *Diagnosis of Tumors and Other Lesions in the Cerebello-Pontile Angle*, THE JOURNAL A. M. A., 1908, i. 1251

In this case, as in others of mine, no deductions could be made from the type of the dizziness as to the location of the lesion. For a short time after the operation it was greater when looking to the right, but soon was equally marked in moving the head in any direction.

As the tumor involved successive portions of the cerebral peduncle, pons and medulla, some interesting symptoms were observed. At first the pupils were normal in size and reactions, but gradually they became larger and irregular, and their reactions to light and movement of the eyeballs became first impaired and then lost, the contraction of the pupils to convergence being retained longest. He developed palsy of the right sixth nerve and drooping of the right upper lid and weakness of the right inferior oblique. There were at first some nystagmoid jerkings in looking to the right and upward, but this may have been due to the weakness of the ocular muscles. Gradually the nystagmus increased, being always greater when looking to the right, less so to the left, and then upward and downward. Toward the latter end of his life the patient constantly kept his left eye closed because he saw double and there was a constant to-and-fro jerking movement of the eyeballs. At first convergence was normal in looking downward, somewhat impaired when looking straight ahead and more so when looking up. As the disease increased convergence became lost entirely, although for a long time the attempt at convergence was retained. It was also noticeable that he developed a protrusion of the right eyeball.

The above symptoms are referable to involvement of the oculomotor nuclei and are of extreme interest. It is presumable that the tumor grew slowly and that gradually the nuclei became diseased. While the growth involved all of the third nuclei many of the cells escaped and the absence of the total implication of the ocular muscles can be explained on this basis. It is interesting to observe that the reaction of the pupils to convergence was lost last. This is due perhaps to the fact that the converging movement is the strongest of the ocular movements and that greater musculature is involved, but it is probable, as I have already suggested,[2] that convergence has a distinct cortical center which is apart from associated ocular movements in any direction, and that just as there can be a paralysis of associated ocular movement upward, downward, to the right or left because of a lesion in the posterior part of the pons and crus, so there can be failure of convergence in similar directions. In the present case convergence was at first lost upward, impaired when looking straight ahead, and normal when looking downward. This I have observed also in other cases.

Nystagmus is fairly constant as a cerebellar symptom, although often I have found difficulty in differentiating between such nystagmus and that due to weakness of ocular muscles. The tendency is to describe any sort of jerking movements of the eyeballs as nystagmus, but I am inclined to differentiate and to ascribe cerebellar nystagmus only to that type in which there are to-and-fro or oscillatory movements irrespective of movement of the eyes, although they may be slightly increased by deviation. The so-called nystagmoid jerkings which are obtained only on looking to the right or left are in most instances due to a weakness of ocular muscles and it very often happens that this may be the first symptom of a succeeding paralysis of ocular nerves.

The protrusion of the eyeball is interesting and is difficult to explain. It has been observed in tumors in practically all parts of the cerebrum and cerebellum and no adequate explanation has as yet been offered.

Both the anterior and posterior corpora quadrigemina were implicated by the tumor growth, but it is difficult to ascribe any definite symptoms to such involvement. Lesions of the anterior corpora quadrigemina supposedly give disturbances of vision, but because of the presence of optic neuritis no deductions can be made. It is supposed that in the posterior corpora quadrigemina the central auditory fibers ascend to the temporal lobe. It was notable that there was disturbance of hearing very early, and while at first it was greater on the left side, it became markedly involved on both. Tests for hearing showed central deafness, but it is difficult to tell whether a lesion of the corpora quadrigemina caused the disturbance of hearing, inasmuch as both eighth nerves were partially diseased and their nuclei were also somewhat involved by the tumor.

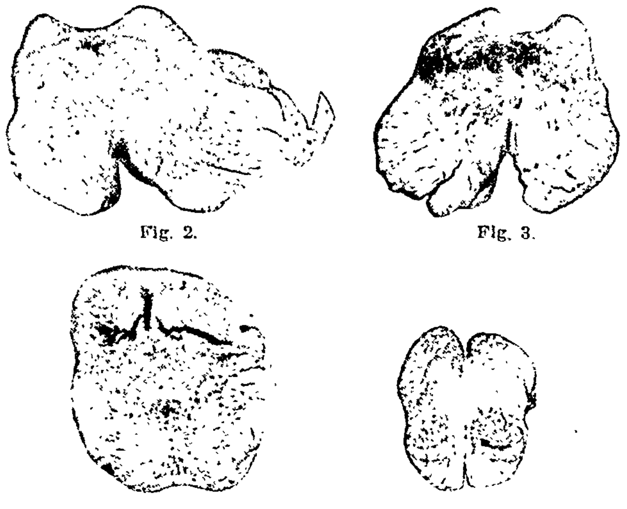

Fig. 2. Fig. 3.
Fig 4. Fig. 5.

Figs. 2, 3, 4 and 5.—The cerebral peduncle, pons and medulla (actual size). Antero-posterior diameter in each is increased and the tumor mass can be seen around the aqueduct of Sylvius and the fourth ventricle in the medulla, staining darkly.

While the growth involved the nucleus of the right fifth to considerable degree and to some extent the left, only the right masseter, temporal and pterygoids were weak.

At first the right facial nerve was involved in its whole distribution; that is, the patient was not able to show his teeth or wink his eye as well as he should, but later the weakness in the upper part of the face disappeared and there remained only the central type of facial palsy. This is difficult to explain, for, while Oppenheim[3] has described in tumors of the pons a weakness first of the central type which finally became peripheral, here we have just the opposite condition, in which at first the upper part of the face was involved as well as the lower, and later there was recovery of movement in the brow. Pathologically both nuclei were involved, the right distinctly more so, but not all of the cells were diseased, and it is possible that the recovery of power in the upper distribution can be explained by the fact that not all the cells were diseased and also that the cerebral fibers were not implicated.

[2] Weisenburg, T. H.: Conjugate Deviation of the Eyes and Head and Disorders of the Associated Ocular Movements in Tumors and Other Lesions of the Cerebrum, The Journal A. M. A., March 23, 1907, xlviii, 1003, 1095.

[3] Oppenheim: Lehrbuch der Nervenkrankheiten, ed. 3.

Examination demonstrated a weakness in the palate and vocal cords; and all through his disease, but especially toward the end, the patient had difficulty in eating, talking and swallowing and dribbling of saliva. All these symptoms can be explained by the involvement of the nuclei in the medulla, although here, as in other nuclei, many of the cells escaped and there was not the weakness that was to be expected from the extent of the pathologic implication. It is also noticeable that there was no disturbance in respiration or in the action of the pulse. Records were kept daily for about a month before his death and observations were taken three times a day regularly.

The patient had some sensory symptoms, being able to appreciate objects better on the left than on the right. It must be remembered, however, that there was considerable involvement of the nucleus cuneatus and gracilis and parts of the median fillet in the pons.

No symptoms can be ascribed to the implication of the posterior limb of the internal capsule and the optic thalamus.

2030 Chestnut street.

ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. SPILLER AND WEISENBURG

Dr. Max Nonne, Hamburg, Germany: It has been the generally received impression that the pulse rate in cerebellar tumors is lowered; but as I doubted by my own experiences the accuracy of this view, I spoke with some of the leading neurologists of Germany, asking their opinions on this subject: replies showed conclusively that, notwithstanding the traditional holding in this regard, the fact is that the pulse is as a rule normal in these cases, or if there is any change it is more often in the direction of acceleration. I should be very glad to learn the experience of American neurologists in this respect. The statements regarding it accord with my own experience.

I should like to call attention to one point in the diagnosis of tumors of the hypophysis, which for some reason has not been touched on, and that is the feminism which is often found in these cases. The voice resembles that of a woman or of an eunuch; the beard falls out, the hair on the genitalia disappears, the penis becomes shrunken and incapable of erection, while the testicles waste away. These symptoms are pointed out by all French and German authors as being of common occurrence in the cases in which the gland itself has been removed, and I have observed such a case clinically and microscopically. I should like a statement of the experience of American neurologists with reference to these symptoms.

Dr. B. Sachs, New York: Evidently Dr. Nonne's experience tallies well with the experience of the majority of us here. As for the occurrence of feminism of which he speaks in case of tumor of the pituitary body, I think we have seen less of it here than is recorded in Germany and France. But in one of the cases which I saw of hypophysis tumor there was distinctly that appearance presented. I believe every one would be struck with such noticeable symptoms as the disappearance of pubic hair, wasting of the genitalia, etc., and that the symptoms would surely have been recorded if present. Far from failing to make a diagnosis of tumor of the hypophysis, one may sometimes make the diagnosis of tumor of this gland when the tumor is elsewhere in the brain; I had an instance of that sort not long ago illustrating this point; a woman was brought into my hospital service when she was near death from brain tumor. She presented all the symptoms that we ordinarily associate with hypophysis tumor, including even a double exophthalmos and some changes indicating an acromegalic condition. An attempt was made to save what little vision was possible by an exploratory operation, but the woman was in poor condition and proved to be one of the few who succumb even to an exploratory operation. We found that the tumor did not involve the hypophysis, but was in the parietal region. So that in rare instances all hypophyseal symptoms may be considered to be secondary symptoms due to pressure on the hypophysis instead of being indicative of a tumor actually involving the substance of the hypophysis.

In connection with the subject of optic neuritis or papillary edema there are unquestionably some conditions difficult to explain. It is difficult to explain why in some cases the optic neuritis appears so early and in others so late, and the condition appears most variable in connection with gliomata. In a patient who was under my direct observation for six years and on whom I had an autopsy performed, during five and one-half years of that period of observation there had not been the slightest trace of any optic neuritis. This was not only the conclusion arising from my own examination, but a most competent oculist repeatedly examined the patient and never found a single trace of optic neuritis. Yet when this man died, having had his tumor for six years and with convulsive seizures as the only symptoms of the tumor, it was found that he had a glioma almost completely filling one hemisphere, and yet no optic neuritis had occurred. The only explanation one can give of those cases is that under slow conditions of growth certain parts of the brain, possibly the optic nerve and the chiasm, accommodate themselves readily to increasing pressure, and the disturbance of function is therefore not so great nor the anatomic distortion so great as one would suppose it likely to be.

In reference to Dr. Weisenburg's point as to whether there is a possibility of making a differential diagnosis between nystagmus due to cerebellar symptoms and nystagmus resulting from insufficiency of the oculomotor muscles: I think there is a difference. First, the nystagmus I have seen in connection with oculomotor palsies has not seemed to me to be quite so rhythmical as that peculiar and rather rapid nystagmus which occurs in connection with lesions of the cerebellum and which I have now learned to associate altogether with an involvement of the dentate nucleus. When I see that peculiar form of nystagmus I naturally conclude that it indicates involvement of the dentate nucleus. We note not only the rapidity and regularity of movement, but also the fact that it seems to be associated with either movement in one direction or another rather than a movement that would seem to imply a defective use of one set of muscles or the other. But I think that this is merely a personal impression, and I should be glad to know whether others have been able to make any further differentiation.

Dr. Julius Grinker, Chicago: In line with Dr. Nonne's observation of feminism in hypophysis tumor, I am reminded of a case of acromegaly, probably due to tumor of the hypophysis, in which feminism was a conspicuous feature. In that case there was also infantilism. The patient was a man of 50 with sexual organs of infantile dimensions. The psychical make-up was strongly feminine in type. I had one case in which, among other localizing signs, ataxia was present on the side in which the tumor was found. In that case there were, besides hypotonicity and adiocokinesis, signs which are mentioned as not frequently occurring in cerebellar tumor, but when present are considered of diagnostic value.

Dr. Theodore Diller, Pittsburg, Pa.: I believe that it is the generally accepted view that in tumors of the cerebellum optic neuritis occurs much more frequently and constantly than it does in tumors of the cerebrum. Recently, through the courtesy of my colleague, Dr. Mayer, I saw a patient under his care who exhibited symptoms of cerebellar tumor, projectile vomiting and marked cerebellar gait, but optic neuritis was absent. Dr. Mayer felt convinced that there was a tumor, and operation was done and a tumor the size of a hulled walnut was found. I ought perhaps to qualify my statement that there was no optic neuritis. There was a slight suspicion merely in one eye which the oculist thought might not be incompatible with a normal fundus.

Dr. Frank Woodbury, Philadelphia: What is the opinion of Drs. Spiller and Weisenburg of the relative frequency of the auditory phenomena in these cerebral tumors? Are auditory phenomena, such as tinnitus and hallucinations of hearing, common as compared with the ocular manifestations? In a case I studied a number of years ago the tinnitus was the most annoying and persistent symptom. The patient also had choked disc and optic neuritis with impaired vision and constant headache, but these symptoms were not so marked as the tinnitus, which the patient described as similar to blowing off steam from an engine, and declared it intolerable. At the postmortem a large growth was found behind the optic thalamus and projecting into the ventricle. It was decided that it was sarcoma and had followed a violent blow on the head some years before.

Dr. James D. Putnam, Boston: I think it would be the experience of all of us that the pulse is oftener fast than slow, although the contrary is occasionally seen, especially in tumors of rapid growth. With regard to the matter of the ataxia on one side in cerebellar cases, I recall an interesting confirmation of that fact, when the question was not of a tumor, but of an abscess of one side of the cerebellum; the ataxia was practically confined to one arm. I recall a case in which the pons at autopsy was found to be so soft that the greater part of it could be almost poured out, and yet within a few months the patient had been walking about the room and using both arms and legs fairly well.

Dr. Hugh T. Patrick, Chicago: I should like to confirm the opinion of Dr. Putnam that the rapid pulse in tumor is more frequent than the slow, except in rare instances. In fact, the other symptoms of tumor are so numerous and well pronounced that the pulse rate as a symptom of tumor may be neglected.

Dr. D'Orsay Hecht, Chicago: Almost all the references in regard to feminism in tumors of the hypophysis are to be found in the French and German literature. We have not recorded many observations on this point, although isolated case reports appear in some recent American contributions. Failure to include this phenomenon in my paper was rather a sin of commission for lack of time than one of omission.

Dr. M. Allen Starr, New York: I can confirm the statement of Dr. Nonne that slow pulse is a rather rare symptom in these cases. I can also confirm the existence of hemiataxia on the side of the tumor in three cases of cerebellar tumor that have come to autopsy and in which that symptom had been very marked. In a case which I saw with Dr. Herman Knapp of New York, in which for several months before her death the ataxia of the woman had been extreme on one side while it was not so on the other, the tumor was found on the side of the ataxia. I have seen confirmed feminism in two cases of hypophysis tumor accompanied by acromegaly. One patient was exhibited before the New York Neurological Society some years ago; the man, who had all the typical symptoms of acromegaly, confided to me subsequently (although he did not wish it known) that his sexual organs had practically withered and that he had lost his pubic hair. His mental type was markedly changed. I watched him for seven or eight years, and his make-up at the end of that time was wholly different from that at the beginning of the disease and would conform entirely to the term used by Dr. Nonne.

I have come to the conclusion (and I think it can be borne out by autopsy records) that the existence of choked disc is wholly dependent on the existence of an effusion into the ventricles of the brain. If there is effusion of fluid into the ventricles and generally a hydrocephalic condition there will be choked disc; without this effusion it will not be present. I have in mind a case of an intimate friend of mine, a boy who grew up with me, and whose mental characteristics I knew intimately, whom I watched through the course of a brain tumor for four years, in whom the diagnostic points of brain tumor were absent. The question was for a long time considered whether he had paresis. At the autopsy, which I made myself, it developed that the right frontal lobe up to the ascending frontal convolution was a mass of glioma. Yet that man had absolutely no choked disc up to the day of his death. He had occasional convulsions; he had no paralysis; there were many mental symptoms present. I have recently seen a patient with a rather extensive glioma of the occipital lobe involving the same distribution shown in one of the specimens passed, in which there was absolutely no choked disc whatever. The tumor, however, had not encroached on the posterior horn of the ventricle, and there was no distention of the ventricle. I think those of us who see many cases of brain tumor at autopsy will agree that if a tumor does not touch the ventricle, when it is a tumor of the hemisphere, or if it is located in such position as not to displace the cerebral axis, so as to cause stasis of fluid in the ventricles, it may exist for a long time without choked disc; but a very small tumor in such location as to interfere with the free exchange of fluid in the ventricles, for instance, underneath the corpora quadrigemina, will cause choked disc to appear early. The early appearance of choked disc is because the tumor interferes with the free passage of fluid through the ventricles and downward.

A point with regard to the diagnosis of the variety of tumor: I agree that in glioma there may be a preservation of many of the functions of the brain, although the glioma lies in a situation where one would expect them to be suspended. One common characteristic of glioma, as distinguished particularly from the harder tumors, is the great variability in the degree of the symptoms. These may be affected by applications of heat to the head or by hot foot baths. The variability of symptoms may be explained by the difference in the degree of the congestion of the tumor; we know that glioma is a very vascular tumor. Deafness on both sides is to my mind very rare indeed in any form of brain disease. I have one case to which I have already alluded, in New York, of bilateral sudden deafness from lesion of the pons, but I still believe it to be a unique case.

Dr. William G. Spiller, Philadelphia: We in America also believe, with Dr. Nonne, that papilledema is a very common sign of brain tumor; but occasionally and perhaps more frequently in glioma than in any other form of tumor, papilledema may entirely fail even to the last stage. The existence of the ataxia on the side of the tumor of the posterior cranial fossa has been demonstrated by numerous cases. The same is true of any lesion in this region.

A case was referred to in the discussion in which the symptoms lasted a very short time. A few years ago I saw a case with Dr. J. W. McConnell in which the first symptom of tumor developed six weeks before the man died. A glioma was found occupying almost one entire cerebral hemisphere.

Nystagmus caused by lesion of the third nucleus, to which Dr. Weisenburg has referred, is probably indistinguishable from that caused by a lesion of the cerebellum, owing to the close connection of the parts; but if the lesion be in the third nerve nystagmus so produced should be distinguished from that caused by a lesion of the cerebellum, as is that caused by a lesion in the sixth nerve when weakness but not complete paralysis of the right abducent muscle exists. The patient looks toward the right, but his eyeballs return because of the weakness, and repeated innervation of the weak muscle causes a jerky movement of the eyeballs resembling nystagmus.

Dr. T. H. Weisenburg, Philadelphia: I have not observed alterations in the pulse rate as a frequent symptom in brain tumor. In the case just reported in which there was great pressure, there being choked disc of 7 diopters, and in which the nuclei of the ninth and tenth nerves were partially involved, there were no variations of the pulse and respiration, although observations were made three times a day for a month before death. I have repeatedly had difficulty in differentiating nystagmus due to an ocular lesion from what I consider pure cerebellar nystagmus. In discuss this in my paper and think that often a greater nystagmus is described when looking to one side, it being ascribed to the fact that the lesion is on that side, when it is really a symptom of weakness of an ocular muscle.

In the present case there were no auditory hallucinations, but it is not at all infrequent to have such symptoms in cerebello-pontile tumors, especially in those which grow from the eighth nerve. I know of no reported cases in which auditory symptoms occurred as the result of involvement of the central auditory fibers.

THE ANTIBODIES IN TUBERCULOSIS AND THEIR RELATION TO TUBERCULIN INOCULATION AND VACCINATION *

WILLIAM J. BUTLER, M.D.
Professor of Medicine, Chicago College of Medicine and Surgery; Attending Physician to Cook County and Willard Hospitals
AND
W. T. MEFFORD, M.D.
CHICAGO

The antibodies of tuberculous patients have been studied by a number of investigators. Arloing discovered a means of obtaining a fluid homogeneous culture of tubercle bacilli. This rendered it possible for him, with Courmont,[1] to study the blood and exudates of tuberculous individuals for their agglutinating action on tubercle bacilli. They found that the serum of many tuberculous patients and the fluid in a large percentage of the cases of pleuritic exudation due to tuberculosis agglutinated tubercle bacilli. This test is termed the serum reaction for tuberculosis. It is said by Courmont to agree quite closely also in positive results with the tuberculin reactions obtained from individuals apparently not tuberculous.

Koch[2] studied the agglutinins of tuberculous serums by a modification of the Arloing[3] technic. He believed that a parallelism existed between the agglutinin content of the blood and immunity in tuberculosis.

Jürgens,[4] on the other hand, investigated the blood of tuberculous patients recovering spontaneously. He was unable to trace any association between their improvement and their quota of agglutinins.

After the discovery by Bordet and Gengou[5] of an indirect method for demonstrating the presence of antibodies by a process known as complement fixation, they applied this principle to the study of antibodies in the blood of guinea-pigs that had been inoculated with killed human tubercle bacilli. They employed an emulsion of tubercle bacilli as antigen and found that the serums of the inoculated animals contained an antibody that would unite with antigen and bind complement.

These complement-binding antibodies were investigated both in animals and in man by Wassermann and Bruck,[6] who used a modification of the Bordet method. They examined extracts of tuberculous tissue both from guinea-pigs and from man and were able to demonstrate that these extracts contained both tuberculin and an antibody, to which they gave the name antituberculin. They examined the blood of tuberculous patients and in 13 of them, who had not received tuberculin inoculations, were unable to find any [illegible] antibodies. On the other hand, th[illegible] blood of eleven tuberculous patients who were being treated with tuberculin contained antituberculin.

They observed that the first series of patients reacted strongly to tuberculin injections, but that the second failed to do so. They attributed the occurrence of the reaction in the first instance to the fact that there were no antibodies in the blood, and that as a consequence the tuberculin was attracted into the focus by the antituberculin existing there free; that as a result of these uniting, complement was taken up, and hyperemia, cell infiltration and softening of the focus resulted; and that as a result of this union the general reaction and local changes of the part occurred. They believed that where antibodies existed in the blood the injected tuberculin was neutralized and no reaction followed.

This theory of Wassermann and Bruck's as to the general and local reaction in the tuberculin inoculation did not seem to be fully sustained by the experimental evidence advanced by them, and was soon attacked by Weil and Nakayama.[7] The latter author's maintained that it was inconsistent that tuberculin antibodies and tuberculin should exist separately in a tuberculous focus at the same time with the former in such quantities as to attract circulating tuberculin. This contention alone, however, could not have great weight, because, as Wassermann pointed out, it is possible to find antigen and corresponding antibodies in the blood at the same time. Weil and Nakayama investigated the tuberculous organ extract as to antituberculin, and stated that they believed the complement-binding observed under these circumstances was due to a summation of less than inhibiting quantities each of tuberculin and tuberculous organ extract.

A substantiation of this latter point, which could but greatly compromise the value of the experimental proof deduced by Wassermann and Bruck in support of their theory, was soon forthcoming in the publication of Morgenroth and Rabinowitsch.[8] They reported that they were unable to find antituberculin in the blood of cases of tuberculosis treated with tuberculin; they were unable to note any difference between normal and tuberculous organ extracts as to their anticomplement action. They referred to the inhibiting action of Koch's old tuberculin alone. They agreed with Weil and Nakayama[7] as to the summation of a non-specific inhibition of hemolysis by organ extract and tuberculin. In view of their negative experimental findings, and from an elaborate argument, based on theoretical grounds, they believed the theory of Wassermann and Bruck as to the action of tuberculin to be unfounded.

Lüdke,[9] on the other hand, reported finding antituberculin in tuberculous organ extract, also in the serums of seventeen out of thirty-one cases of tuberculosis treated by tuberculin. He noted that those who had antibodies in their blood showed no or very slight reaction to tuberculin injections, while those who failed to show antibodies gave a marked reaction. He examined eight tuberculous patients before and after tuberculin treatment, and was able to demonstrate antibodies in seven of them, only after tuberculin treatment had been used. He noted, also, that he found antituberculin in few patients who had not had specific treatment. The results of his experiments were practically the same as those of Wassermann's and Bruck's.

Citron[10] examined a number of cases treated with tuberculin. In 6 of these, antibodies were not found and 5 of them reacted to tuberculin; of 8 cases, with the blood of which he obtained the complement-binding reaction, 6 failed to react to tuberculin. He and Wassermann had also observed antibodies in a case that had not received tuberculin treatment. Confirming Wassermann and Bruck's investigations, he concludes that antituberculin is, as a rule, not demonstrable in the

serum of tuberculous patients, but that occasionally, owing to unknown causes, it may be found; that those patients who are treated systematically with tuberculin and who lose in the course of their treatment their original reaction for tuberculin, regularly show antibodies in their blood, on account of which he attributes the absence of reaction to tuberculin injections; that antibodies almost always fail in the serums of those tuberculous patients who still react to tuberculin; that in the latter cases the tuberculin that enters the circulation is abstracted from it by the antibodies present in the diseased focus, on account of which the local and general reaction result.

Christian and Rosenblat[11] have studied this question in animals. They observed that the serums of animals that had been immunized with tuberculin or infected with tuberculosis agglutinated tubercle bacilli. Under these conditions, however, they failed to find antituberculin. If the tuberculous guinea-pigs were injected with tuberculin, antibodies appeared in their blood; such guinea-pigs were found to be less resistant than those that had not been treated. If tuberculin injections were begun on the second day after infection, the pigs lived a couple of months longer than the control animals. They refer this lowered resistance in late employment of tuberculin injections to a negative phase and suggest that where it is possible, as it is in man, to bring them through to a positive phase, healing of the tuberculosis might result. They believe with Wassermann that the antituberculin bodies are produced in tuberculous tissue. In support of this they cite experiments in which many of the tuberculous glands of infected guinea-pigs were removed and thereafter a disappearance of antituberculin from the blood was observed.

Engel and Bauer[12] were unable to demonstrate complement-binding antibodies in the blood of tuberculous children before inoculations with tuberculin. With tuberculin treatment the antibodies were found quite uniformly increasing with the immunity of the child against larger doses of tuberculin.

Weil and Strauss[13] examined by the complement-deviation reaction the bloods of thirty-three patients with pulmonary tuberculosis who had been treated with tuberculin for several months. They concluded that the presence of antibodies in the blood did not go hand in hand with the disappearance of the tuberculin reaction, but, on the contrary, were most frequently found in those who reacted strongly to tuberculin injections. At the same time they did not believe that the hypersensitiveness to tuberculin was attributable to those antibodies. They believe that antibodies are present in tuberculosis because of the existence of a hypersensitiveness, anaphylaxis, and not because the latter is due to antibodies. They consider that the action of tuberculin, instead of being cleared up by the theory of Wassermann or by the bacteriolytic theory of Wolff-Eisner,[14] remains an unexplained phenomenon.

The hypersensitiveness to tuberculin, as exhibited by the skin reaction of Pirquet, was investigated by Czastka with relation to the complement-binding antibody content of the blood. Twenty tuberculous patients were examined, fourteen of whom had not been treated with tuberculin. In four of the latter antituberculin was found, three of these giving the tuberculin skin reaction. Seven of the remaining fourteen cases gave a positive Pirquet reaction. Of the seven patients treated with tuberculin, three showed antibodies in the blood. Two of these gave a positive Pirquet reaction on first vaccination, the third patient reacting slightly after the second vaccination. Of the other four cases not showing antibodies, three gave a positive result.

Czastka[15] concluded that complement-binding antibodies did not bear any relation to tuberculin treatment, or to the Pirquet reaction; that in view of the uncertainty that bacteriolysins exist against tubercle bacilli, and especially against heated bacterial fragments, the bacteriolytic theory of Wolff-Eisner was unfounded. Wolff-Eisner and Ascher observed that the majority of the tuberculous patients they examined showed complement deviation, and that it was impossible to trace any close relation between this and the results of the skin and conjunctival reactions. They questioned the specificity of the complement-binding reaction in tuberculosis, having found it in other infections.

Cohn[16] noted an absence of antibodies in the early stage of tuberculosis in 14 cases, but obtained a complement deviation reaction in 15 of 53 cases in the second and third stages of tuberculosis which had not been treated with tuberculin. He was unable to demonstrate tuberculin in the blood of patients with miliary tuberculosis, as reported by Lüdke and Bruck. He did not observe any relation to exist between the presence or absence of antibodies in the blood and the reaction of the patient either to tuberculin treatment or to general or local reactions from tuberculin.

In view of the evident uncertainties and the failure of agreement in the results presented by various observers concerning the complement-binding antibody and its relation to tuberculin reactions and tuberculin therapy, and recognizing the importance of the establishment of such a relationship, if possible, we examined a number of cases of tuberculosis with a view to investigating the complement-binding antibody content of the blood of patients who had not and of those who had received tuberculin inoculations and also to see if these antibodies bore any relation to the results of the tuberculin skin reaction. We have also ascertained the opsonic content of the blood in some of these cases with a view to determining its relation to the complement-deviation antibody and likewise its relation to the skin reaction.

The bacteriolytic theory of Wolff-Eisner concerning the skin and conjunctival reactions appears to be unsupported by any experimental evidence. Zieler[17] has recently shown that old tuberculin which has been completely freed from all tubercle bacilli fragments, provided any had existed in it, gives a stronger reaction, if any difference can be noted, than the old tuberculin not so treated. Also these reactions were obtained from material separated by dialysis from tubercle bacilli emulsion. Zieler found that the histologic changes of the skin in the Pirquet reaction were practically the same as those that follow infection with tubercle bacilli.

The technic employed in applying the complement-deviation reaction for antibodies in tuberculosis is the same as that used in demonstrating the complement-binding substances in syphilis, except that in tuberculosis old tuberculin, an emulsion of tubercle bacilli, or an extract of a tuberculous organ is used as antigen. Koch's old tuberculin is the most frequently used and apparently is the most satisfactory. The inhibiting properties of old tuberculin alone are very pronounced. On this point Morgenroth and Rabinowitsch lay much stress. We found, also, that sometimes small quantities of tuberculin would inhibit hemolysis. Cohn also has observed that smaller quantities sometimes inhibited more than larger in the test and mentions this as an argument against the contention of Weil and Nakayama that a positive specific complement-deviation reaction may occur through a summation of two non-specific inhibiting substances. The old tuberculin[18] employed by us in our examinations had to be used in smaller quantities than those reported by many authors. We found that 0.2 c.c. and sometimes 0.1 c.c. of old tuberculin strongly inhibted hemolysis, necessitating reduction of the amounts to 0.05, 0.025 and 0.0125 c.c.

Tuberculous serums, as well as the serums of many normal and diseased individuals, sometimes inhibit hemolysis alone, which likewise often requires the amount of serum used to be reduced; on the other hand, occasionally a larger quantity of serum may not exert this inhibiting action because of its possessing amboceptor for sheep's corpuscles.

The protocol of an examination of a tuberculous serum giving a positive reaction would read as follows:

Antigen.	Serum.	Guinea-Pig Serum.	Rabbit Serum.	Sheep Corpuscles Emulsion, 5 Per Cent.	Result Hemolysis.
0.05	0.1	0.1	0.002	1	No
0.05	0.2	0.1	0.002	1	No
0.025	0.1	0.1	0.002	1	No
0.025	0.2	0.1	0.002	1	No
0.05	...	0.1	0.002	1	Yes
0.025	...	0.1	0.002	1	Yes
.....	0.4	0.1	0.002	1	Yes

In each test, control serums of normal individuals are included and put through the same series of examinations as the tuberculous serums. We have not infrequently seen a considerable binding of complement with a serum from an apparent normal.

The cases herewith reported were cases of pulmonary tuberculosis in the second and third stages.

TABLE OF COMPLEMENT-DEVIATION REACTIONS IN TUBERCULOSIS

Case. No.	Complement Deviation Test.	Opsonic Index.	Pirquet Reaction.	Treatment Tuberculin. T. R.
38	+	1.32	+	Yes
39	..	0.56	+	Yes
40	..	0.17	+	Yes
42	..	0.73	..	Yes
43	+	0.51	+	Yes
44	+	0.76	+	Yes
51	+	0.8	..	Yes
45	..	0.99	..	No
46	+	0.76	..	No
47	+	0.88	..	No
71	+	0.98	+	No
72	..	0.69	+	No
73	..	0.3	+	No

Of five cases of tuberculous joint and bone disease, two gave a positive complement-deviation reaction. None of the patients received tuberculin. The patients who were being treated with tuberculin were examined on the day they received their injections. As they were receiving injections twice a week the blood examinations would come on a day that would correspond to a high tide of immunity in the opsonic sense. This point is of importance, as we have learned from a study of opsonins that in the interim of inoculations a negative and positive phase, with regard to index can usually be made out, and various antibodies usually increase at the same time. All but five of the patients examined by us had pulmonary tuberculosis. It is not always possible in such cases to secure from inoculations the negative and positive undulations, because of the factor of auto-inoculations. In the few cases in which we made a single record it will be observed that in only one was the index found above normal. In regard to the complement-binding antibodies of the blood of patients treated with tuberculin and those not so treated, we found that 4 out of 7 who were treated with tuberculin and 3 out of 6 who were not receiving tuberculin gave the reaction. Of the tuberculin-treated cases, three of four that gave the complement-deviation test gave a positive Pirquet reaction, and in one of the latter the opsonic index was above normal. Of the untreated cases, one of the three that had complement-binding antibodies gave a positive skin reaction. Of three of the untreated cases that did not show antibodies, two gave a positive skin test.

CONCLUSIONS

As a result of our work, we believe the following conclusions justified:

No relation exists (first) between the complement-binding antibody and tuberculin inoculations and vaccinations; (second) between the complement-binding antibody and the opsonic index; or (third) between the opsonic index and the tuberculin skin reaction.

Not only have our examinations failed to show any relation between tuberculin antibodies and tuberculin reactions and inoculations, but, *on account of observing* occasionally an inhibition of hemolysis with normal serums, we are strongly inclined to believe that the complement-binding reaction is not specific for tuberculosis.

OLIVE-OIL FOR POSTANESTHETIC NAUSEA*

EVARTS A. GRAHAM, M.D.
Nicholas Senn Fellow in Surgery, Rush Medical College
CHICAGO

It has been shown in work soon to be published that fats and other ether-soluble substances, when introduced into the alimentary tract of individuals subjected to ether anesthesia, are capable of restoring to the blood certain properties which are inhibited by the action of the drug, viz.: those concerned with the phenomena of phagocytosis. With the idea in mind that other effects of ether, such as nausea and vomiting—whether these be due to a local irritating action of the drug on the gastric mucosa or to a more general action elsewhere—might also be influenced by the introduction of a fat, such as olive-oil, into the stomach, in a series of cases, patients were given olive-oil by mouth immediately after partial restoration of consciousness following an ether anesthesia. Up to this time thirty patients in all have been treated in this manner. The results have been striking. In certain of the cases nausea failed to occur at any time. In a second group in which nausea had begun prior to the administration of the oil it was immediately checked by this treatment. In only one of the thirty cases was nausea observed after giving the oil. In this case consciousness had been regained, and nausea and vomiting had set in. One ounce (30 c.c.) of olive-oil was then given by mouth. Almost immediately the patient remarked on the "soothing" sensation produced by the oil. Nausea and vomiting ceased and remained absent for ten hours, at the end of which time there was a return of the symptoms in a mild form. The cases chosen were all simple, so-called "clean," surgical cases in which the probability was strong that such nausea as

[18] The old tuberculin was received from the experimental department of Parke, Davis and Company.

* A Preliminary Report from the Department of Surgery, Rush Medical College.

Clinically such conclusions are based largely on the frequent occurrence of intestinal lesions in artificially fed infants, but the direct proof of this route of infection naturally rests on animal experiments.

Chauveau,[1] who was the first to demonstrate the infectivity of the human bacillus for cattle clearly proved this method of infection, as did later Nocard,[2] Tjaden[3] and Cipollina,[4] by using kittens, young pigs and monkeys as well as cattle in their feeding experiments.

The still further disputed question of whether a lesion of the intestinal mucosa is necessary for infection by this channel has also been approached in a similar manner. Dorbroklonski[5] introduced cultures of tubercle bacilli into the stomach of normal guinea-pigs, and from a most careful microscopic as well as macroscopic examination of the entire digestive tract concluded that living bacilli were capable of passing through the perfectly normal intestinal mucosa of guinea-pigs and that no lesion of any description was necessary. Similarly Ravenel[6] was able to recover virulent bacilli from the chyle of previously healthy dogs fed with cultures mixed with melted butter as early as three and one-half to four hours after feeding.

From these and various similar experiments it would appear undoubtedly that not only is the intestine frequently the portal of entrance for the bacilli, but that in the lower animals, at least, infection may occur through a perfectly normal intestinal mucous membrane.

In man, however, this is particularly difficult to demonstrate because at autopsy there is most frequently present either, on the one hand, an advanced stage of the disease with multiplicity of lesions which makes it impossible to detect with certainty the primary source of infection or, on the other hand, a rapidly fatal process confined to the lungs alone.

The findings in the present case noted in a routine post-mortem examination under circumstances which rendered a particularly careful examination of the parts affected necessary are of interest from the fact that, while the conditions noted arose in a wholly natural manner, they resemble those produced in the experiments quoted and bear closely on the results.

Subject of Examination.—This was a colored man, aged 32, a patient of the State Hospital at Trenton for three years previous to his death. He was a general paretic, dull, stupid and much deteriorated, and untidy and filthy in his habits. He was placed in a ward occupied by other negroes, many of whom were similar in general behavior. His mental condition and habits offered excellent opportunity for infection by the intestinal tract. His last illness was cardiac weakness from chronic myocarditis. There was no loss of weight or other suggestion of any constitutional disorder.

Autopsy.—Examination of the thorax showed the pericardium and pleuræ to be normal. The heart muscle was the seat of atrophic and interstitial changes. The lungs were both considerably engorged and the dependent parts showed some partial lobular consolidation. No nodules, pleural scars or thickenings were present. There was no macroscopic indications of tuberculosis and the peribronchial glands were not unusual. The general abdominal cavity was likewise negative. Both the parietal and visceral peritoneum was free from adhesions or exudate. The liver and kidneys were affected with early interstitial changes.

The pancreas, adrenals, bladder and prostate showed nothing abnormal.

For the reason that, at the time the autopsy was made, an outbreak of typhoid fever was feared in the institution, an unsuspected case having been discovered at autopsy shortly before, special attention was given to the intestinal tract, spleen and mesenteric lymph-glands. The latter in the region of the lower three feet of the ileum were greatly enlarged, about six or eight of the glands being as large as walnuts; others were about the size of a pea, and a few similarly enlarged glands were found at the root of the mesentery.

Typhoid was immediately suspected, although the spleen was quite small and firm, and the intestine was most closely examined, both externally and internally, for any variety of lesions.

Practically nothing was found. The mucosa of the duodenum, jejunum and large intestine showed indefinite areas of blood stasis only.

The mucosa of the ileum was smooth and pale throughout; there was not the slightest indications of injection, erosion, ulceration or enlargement of Peyer's patches or solitary follicles. The serous coat everywhere appeared normal.

A careful examination of a smear preparation from an enlarged mesenteric gland showed tubercle bacilli in limited numbers and a large part of the ileum opposite the affected lymphatics was saved for microscopic examination. The other organs, including the brain, heart, lungs, kidneys, pancreas, adrenals, and lymph-nodes, were examined microscopically.

Cultures on agar were taken from the liver, spleen, bile and mesenteric glands; colon bacilli only were found.

Microscopic examination of the pancreas, adrenals, liver and kidneys showed no lesion of importance in connection with the special findings. There was a moderate grade of chronic interstitial overgrowth in liver and kidneys, but no indication of tubercle formation.

Sections from all of the more suspicious looking areas of the lungs showed merely an engorgement and edema with a moderate cellular alveolar exudate; an early simple broncho-pneumonia incidental to the cardiac condition without any special characteristics.

A satisfactory examination of the intestine was possible, the autopsy being performed only two and one-half hours after death. Extended examination of sections from the ileum at different levels along the lower third, including the entire circumference, showed the mucous membrane to be the seat of early post-mortem alteration, but entirely free from erosion or ulceration. No indication of infiltration or hyperplasia was found in the submucous lymphoid tissue or follicles. The intestinal findings were pronounced negative only after prolonged search.

Two organs contained tuberculous lesions, the spleen and mesenteric glands. In the latter the process was fairly well advanced, the largest glands showing massive central coagulation necrosis with very little unaffected tissue remaining; the smaller glands showed numerous giant cells and scattered solitary tubercles in which tubercle bacilli were demonstrable after alcohol fixation.

The spleen, though macroscopically negative, showed a condition somewhat similar to that in the more slightly affected lymph-nodes, though even less advanced.

Scattered through the pulp were fairly numerous incipient tuberculous foci, represented by small collections of epithelioid cells, with an occasional giant cell or minute area of necrosis. The number of lesions was considerably greater proportionately than the apparent age of even the more advanced individual tubercles. The lesions in the spleen suggested a very recent but rather severe infection. As before indicated, no lesions in any way suspicious of tuberculosis were found elsewhere.

Notwithstanding the fact that no lesions, tuberculous or otherwise, were found in the intestine, the case is regarded as one of primary infection through this organ.

It is realized that tuberculosis of the mesenteric glands *per se* is not necessarily an indication that the channel of infection was the intestine, and that these are not only frequently but commonly infected in processes of a general nature.

On the other hand, it is certainly a recognized characteristic of tuberculous infection generally that involvement of the regional lymphatics is the best guide to the original point of infection; and this applies more particularly to cases such as the present, in which the infection is recent and the areas limited.

This view is based not merely on human autopsy findings, which in themselves are sufficiently numerous to support the view, but on exact experimental methods as well.

Among the investigations in human subjects may be mentioned the work of Heller,[7] who, in order to approach the question of primary intestinal tuberculosis, examined the bodies of 714 persons dead of diphtheria, and based his opinion that about 31 per cent. of the tuberculosis found was primarily intestinal on the tuberculous condition of the mesenteric glands.

On the experimental side, among others, are the works of Tjaden[8] and Schottelius,[9] who in all their animals fed with tuberculous material found a marked tuberculous mesenteric adenitis as well as larger lesions of the lungs, pleura and other viscera.

Schroeder and Cotton[10] considered that the mesenteric tuberculosis found in a calf subcutaneously inoculated with tubercle bacilli (a severe tuberculous bacteriemia) was due either to direct transmission of infection from the seat of inoculation or from bacilli coughed up from the lung and swallowed. In this animal the lungs were heavily infected.

If in the examples quoted the conclusions relative to intestinal and mesenteric lymph-gland infections can be accepted, certainly in the present case, in which no tuberculous foci, however small, were found either in lungs, bronchial glands or other organs which might create doubt, the assertion that the infection entered through the unaltered intestinal mucosa and first manifested itself in the regional lymphatics may be accepted, the only alternative being that the case was of the type of *typho-bacillose* of Landouzy,[11] which from both the clinical history and post-mortem findings seems extremely unlikely.

Two points are worthy of emphasis:

1. An unquestionable instance of primary tuberculous infection through the intestine in an adult individual, as shown by the marked foci in the regional lymphatics.
2. The passage of active tubercle bacilli through an intestinal mucosa which to both macroscopic and microscopic examination showed no trace of a demonstrable lesion.

The presence of multiple additional foci in the spleen indicates the manner in which the infection was progressing; had the disease been allowed to continue its course it would have doubtless terminated in a diffuse miliary tuberculosis without definite suggestion of the primary source of infection. But, as previously stated, the purely accidental discovery of the condition at the exact stage when of sufficient duration to make perfectly clear the process without obscuring the true significance gives to the case the definiteness of experimental observations along similar lines, and offers a demonstrable proof and natural illustration of what must be of frequent occurrence, though seldom capable of so direct demonstration, in man.

RECENT FINDINGS REGARDING THE DISTURBING ELEMENTS IN MILK FOR INFANTS *

FRANK C. NEFF, M.D.
KANSAS CITY, MO.

The editions for 1909 of Holt's "Pediatrics" in this country and of Still's "Diseases of Children" in England, together with the current literature, give no evidence, so far as I can find, of any change in the commonly accepted opinion that it is the excess and the inadaptability of the casein in cow's milk and the low percentage of fat that cause the chief inherent difficulties in the administration of milk. Likewise there is no change from the belief that the sugar of cow's milk creates no disturbance, especially if the percentage be increased by the addition of cane-sugar or milk-sugar to a point approximating the amount contained in human milk. Koplik refers to the fact that the salts of cow's milk, chiefly lime and potassium, are not well assimilated, fully 34 per cent. being excreted.

So the recent studies in Germany must be regarded as revolutionary, and perhaps evolutionary, since they regard the casein of cow's milk as perfectly harmless and place the responsibility for the digestive difficulties on the salts, sugar and in some conditions the fat (the latter being the chief cause in the exudative diathesis and those diseases described as "dyspepsie" and "decomposition.") During the last few years Professor Finkelstein and his colleagues, Myer and Rosenstern, have been carrying on investigations at the Berlin Kinderasyl, probably the largest hospital for infants in the world, studying the metabolism and pathology of infant-feeding. Their findings are, in the main, accepted by most of the pediatrists of Germany, and have been confirmed by some of the other investigators. It is to the kindness of those in charge at the Kinderasyl that I am indebted for the privilege of seeing the work being done on this subject.

REGARDING THE SALTS OF COW'S MILK

The salts of cow's milk which are of importance are sodium, calcium, potassium and magnesium chlorids, and they are three and one-half times as abundant as in human milk. In contradistinction to the salts in human milk, they frequently act as a direct poison to the child, even when reduced to the same or lower percentage found in breast-milk. Sodium chlorid in physiologic solution has been proved by Finkelstein to be a poison to sucklings when given internally. Intravenous injection of the same causes fever, acting, it is supposed, directly on the heat centers. The salts of cow's milk have been proved experimentally to react badly on the baby on account of the antagonism between the sodium and the calcium. The salts of the milk most easily taken care of by the infant are the calcium chlorid and magnesium chlorid in combination. The potassium chlorid and the sodium chlorid are antagonistic. Infants of suckling age react more to salts than older children. If sodium chlorid is given a clinical reaction occurs, marked by a slight rise in weight, while with the calcium chlorid a decrease in weight occurs. If 100 grams sodium chlorid solution is given internally the temperature goes up to 104 F. in from four to six hours. The calcium salts alone give a subnormal temperature, but when combined with sodium chlorid a rise of temperature results, and is thought to be from an antagonistic combination of the sodium and calcium which is unfitted to the child's digestion and acts as a poison. Sixty per cent. of the bottle-fed infants in Germany have a tendency to convulsions, a condition called spasmophilia. This is manifested by an oversensitiveness in the electrical reactions, an overexcitability to the open cathode pole. When the infant reacts to less than five milliampères, the pathologic condition of spasmophilia exists. Experiments with the various elements of cow's milk have been made. When casein or fat or sugar alone are given, no electrical overexcitability appears, but when the salts of the milk are fed the infant reacts to less than five milliampères. Other manifestations of spasmophilia appear in the salt-susceptible infant, such as the facial phenomenon (Chvostek's) and Trousseau's symptom of spastic contraction of the hand, all of which disappear when the food is salt-free.

---

* Read before the Jackson County Medical Society, Oct. 19, 1909.

SUGAR DISTURBANCE

A distinct clinical type of infantile disturbance has been investigated and described by Finkelstein[1] under the name of sugar intoxication. The condition is not an intestinal infection, but depends on the presence in the food of the sugar of cow's milk and its intolerance by certain infants. The elimination of the sugar causes the disappearance of the symptoms and a return to health. The sicker the child the less sugar required, it has been shown experimentally, to cause the acute condition. Infants suffering from the various stages of intestinal and nutritional disturbances leading up to marasmus are more susceptible to sugar intoxication, and they react with an elevation of temperature when sugar alone or milk containing sugar is given. The other symptoms are made constantly worse, and we find the infant presenting the following:

1. A general appearance of collapse.
2. A sort of coma, lasting a minute, resembling in some ways a meningitis. The child pays no attention to surroundings and sleeps all of the time, appearing benumbed.
3. A sudden drop in the weight.
4. Fever. This is always present, irregular, but comes up suddenly as high as 104 to 105.8 F.
5. A leucocytosis of from 25,000 to 60,000.
6. Sugar always present in the urine. It is an alimentary glycosuria, due to inability of the blood to oxidize the sugar.
7. Changes in the character of respiration. It becomes coma-like, irregular, but with a characteristic lengthening.
8. Diarrhea with green fermented stools, as many as eight daily.
9. Albumin in urine. There is no acidosis or butyric acid, as is found in diabetes. The sugar acts in these cases as a direct intestinal poison and as the cause of the series of symptoms.

The administration of weak tea and water and the withdrawal of all sugar will cause a prompt disappearance in twenty-four hours of all the symptoms in the milder cases, the severer cases requiring longer; then small feedings of breast-milk should be given for fourteen days, or, if the child is bottle-fed, no sugar should be given until the end of that period. Malt-sugar is found to be better tolerated in these cases than cane-sugar. Milk-sugar is the least tolerated, and in general has the least influence on body growth.

SUMMARY

The following points are proved:

1. The salts of cow's milk have a pathologic influence on the infant, causing a condition of spasmophilia or tendency to convulsions, which may go to a spasm of the glottis, tetany or an eclampsia. The treatment consists simply in feeding for a period with a salt-free diet.
2. The sugar of cow's milk is not tolerated by some infants, acting as a poison and causing a distinct symptomatology, a condition called sugar intoxication, which disappears promptly on the elimination of sugar from the food. It is also associated at times with those disturbances, the most extreme of which is marasmus, in which the infant has an intolerance for fat. The hunger-cure is practiced in these conditions, either the sugar or the fat or both being eliminated from the milk until the symptoms have improved.

SODIUM NITRITE IN BRONCHIAL ASTHMA

GEORGE EDWARD BARNES, B.A., M.D.
HERKIMER, N. Y.

Few pictures of human suffering have so stirred up the pity and despair of the physician and demonstrated a single shortcoming of therapeutics as have obstinate attacks of bronchial asthma. What a boon to both patient and doctor would be a drug to relieve the spasm of the bronchial muscles! The narcotic agents used for this purpose—morphin and chloral—are not suitable for frequent use and are not always reliable. Potassium iodid is not often efficient. The ordinary antispasmodics are impotent. Inhalation of the smoke of potassium nitrate, stramonium, etc., often fail to bring relief and are detrimental because they irritate the bronchial mucous membrane. Amyl nitrite and nitroglycerin often give some relief, but their effect is fugacious.

I recently attended a patient who had been afflicted with asthma for forty-six years. His last attack was complicated with a coryza and trachitis and a very severe laryngitis. I treated the combined conditions for about ten days with various drugs and produced some improvement in the inflammations, but scarcely any improvement in the breathing. It then occurred to me to try sodium nitrite. I administered one grain of it by mouth, and in about half an hour the dyspnea diminished and the radial artery, which had been contracted, became somewhat relaxed. Two hours after the first dose the patient received another grain, and in about half an hour he was breathing naturally and the pulse was soft. Thereafter the patient took one grain of the sodium nitrite about every two and one-half or three hours for two days, and then the intervals were gradually increased until, after about a week, he limited the use of the medicine to one dose at bedtime, and thus continued it for several days. As soon as the sodium nitrite relieved the spasm I began to treat the patient's nervous system. The asthma did not recur, but the laryngitis long persisted.

Another recent case of bronchial asthma occurred in a man 64 years of age who had had the disease since youth. When called, I found the patient sitting bent far forward, his elbows resting on his knees. Every act of respiration was performed with the greatest muscular effort and by a slight rhythmical raising and lowering of the body. The patient's face expressed helplessness and weariness from effort, lack of sleep and the impossibility of eating. His pulse was tense. He had been taking medicines without the slightest benefit. I gave him one grain of sodium nitrite and after about half an hour there was slight improvement. One hour after the first dose I gave a second one, and about half an hour after it the patient was very much relieved. He continued to wheeze slightly, but he could breathe with considerable ease and could rest against the back of his chair. He began to yawn and soon fell asleep. He continued for a few days to take one grain of the drug every two or two and one-half hours and enjoyed comfort about the house and on the street. I saw him a week after my first call and he told me that he was taking occasional doses of the drug. He then passed from my observation. I gave him also constitutional treatment, for asthma is primarily a nervous affection which may be started by numerous stimuli of discomfort.

---

[1] Monographs by Finkelstein and his assistants may be found in the Berlin Jahrbuch für Kinderheilkunde during the past two years.

In the severe cases of asthma the initial dose of sodium nitrite should probably be two grains by mouth. The drug may be given hypodermically when dyspnea is severe. It is a remedy of marked action on unstriped muscle and should be given with discretion. The limit of dosage is indicated usually by a feeling of distention of the head and then headache.

RECURRENT VOMITING WITH ACETONURIA

REPORT OF TWO CASES

THOMAS J. BURRAGE, A.M., M.D.
PORTLAND, ME.

The occurrence of two cases of recurrent vomiting in members of the same family, a brother and sister, is my apology for offering the following report:

Case 1.—The elder of the patients is a boy of 7, rather small, as his parents are, but active and vigorous, though of a distinctly neurotic disposition. He was delivered at term by instruments, and nursed for six weeks with poor success. From that time on he passed through the hands of various physicians, who tried in vain to find a suitable milk modification. During this time he was constantly subject to vomiting, colic and indigestion. Measles and whooping-cough have been his only other sicknesses. The mother, who is a keen observer, thinks that the child has always had this type of vomiting, because of its severity and associated prostration. It was not until the boy was in his fifth year, however, that acetone and diacetic acid were first demonstrated in the urine, and a correct diagnosis established. Since this time the patient has been seen in some ten attacks, though he has had many others, and at these times acetone has always been detected on the breath and in the urine. Recurrence has taken place in from five weeks to five months, and attacks have usually lasted four or five days, being attended by almost constant vomiting, marked emaciation, and prostration. During the last nine months he has had only three attacks, but one in the summer, of marked severity, was accompanied by considerable hematemesis. As the child grows older, attacks are becoming less frequent and according to the usual progress of such cases, should cease within a year or more.

Case 2.—The sister of the first patient is now 3 years and 9 months old, and is of the same type as her brother—small, thin, active, and neurotic. She was born without instruments and nursed for nine months, with occasional substitute cow's milk feedings. She suffered less from vomiting and indigestion than her brother did, but experienced considerable difficulty when put on cow's milk entirely. It was then found that her capacity for fat was decidedly limited, and it was a number of months before she could take whole milk. Like her brother, she has had measles and whooping-cough. At about a year and a half she had her first attack of severe vomiting, which was accompanied by acetonuria. Since then she has had four recurrences, all associated with prostration, moderate emaciation, and the presence of acetone and diacetic acid in the urine. It is noticeable that these attacks are not as yet so severe as those of her brother, though it is possible that they may be as the child grows older. During the last recurrence, which was of recent date, the vomiting was of only moderate severity, but more stupor than usual developed, and delirium, lasting for about an hour, made its first appearance. In prognosticating the future of this case, it would seem probable that the child will follow a course similar to that of her brother, inasmuch as ordinary methods of treatment, diet, and hygiene seem to have little effect on the course of the disease.

139 Park Street.

Therapeutics

CHOREA

The condition to which this name is applied is so little understood that Dr. George Montague Swift's discussion of it in the *American Journal of the Medical Sciences*, for September, 1909, should attract special attention. He declares chorea, i. e., incoordinate, involuntary muscular movements, to be a symptom and not a disease. Also asserts that large doses of arsenic are dangerous. Swift has seen from the arsenical treatment of chorea hemorrhage from the stomach, hemorrhage from the kidneys, severe irritation of the conjunctivæ, and neuritis. It is no uncommon thing to see tedious gastrointestinal inflammation and albuminuria, showing kidney irritation, from large doses of arsenic. Serious anemia can also be caused by pushing arsenic, and neuritis, even general multiple neuritis, may be caused by the misuse of this drug.

Swift believes chorea to be a symptom of several kinds of cerebral irritations, and he divides the causes, in children, into two principal classes. In Class 1 the symptom of chorea is caused by too great mental and physical activity, and consequently mental tire. In Class 2 the cause of the symptom of chorea is an infection.

Class 1 is probably the larger class, and the muscle contractions and incoordinate movements are a symptom of debility caused perhaps by a severe illness, or more frequently by overwork in school or at home, in the endeavor of parents to push their young girls, especially, to acquire quickly various accomplishments, added perhaps to the fad of the age for an undue amount of physical exercise. In other words, the young girls, and the boys also, have but few periods of rest, and hasten, as do business men and society women, from one appointment and occupation, pleasure, exercise or function to another, as rapidly as possible. Even in the home something is doing every minute. Soon these poor tired children begin to eat insufficiently, do not sleep well, and become anemic and chlorotic.

Even very young children, babies, have too much done for them, are amused too much, talked to too much, played with too much, and, as Swift says, are walked too much. The result is nervous exhaustion. There may be tantrums and explosions of temper, but all represent brain and nerve tire, and the choreic movements are but symptoms of this condition.

Swift puts such patients "to bed in a quiet room, relieves their anxieties," aids sleep, if necessary, and "stuffs" the patients with nutritious food. He administers iron, bone marrow, fats, and cod-liver oil, if advisable. If the choreic movements are sufficient to cause restlessness and prevent the child from sleeping, he gives, temporarily, sedatives, as "bromids, codein, and trional or veronal" sodium. Just as soon, however, as there is some improvement he sends the patient into the country or to the seashore for fresh air and quiet.

There is no question of the advantage of the fresh air and rest cure for these patients; in fact, it is often best to move them, even though quite ill, and the seashore and the sea breezes are probably better than country air for them. All the various addenda to the rest cure for neurasthenia should be taken advantage of as soon as possible, viz.: warm, non-stimulating baths, massage, and later graded simple physical exercises.

Swift's second class of causes of choreic movements is the class due to infections, which may be "rheumatic, malarial, pneumococcic, or typhoid." He well says that since there are probably several varieties of germs which cause rheumatic affections, there are probably several varieties of these rheumatic germs that cause a development of choreic movements. Such infections, especially the rheumatic infections, predispose to endocarditis and even pericarditis. These infections may cause sufficient anemia, malnutrition and irritation of the nervous centers to account for the muscle contractions. The endocarditis develops slowly in these cases and should be carefully watched for, and Swift thinks that a weakened heart from these infections can become suddenly dilated by any severe muscle exercise, and even by a severe nervous strain, as by a tantrum.

In these patients, of course, rest in bed is imperative. The medicinal treatment depends on the germ that is infecting the patient. All channels of entrance of infection should be removed as soon as possible, such as "diseased tonsils, postnasal adenoids, and decayed and decaying teeth." Gastrointestinal fermentation should be prevented.

It is probable that the germs that cause rheumatism and the chorea of infection may enter the blood not only through the tonsils, but often through the intestines, and the drugs found most advantageous in stopping the disease of rheumatism and the so-called disease of chorea, such as salicylic acid in the first instance and arsenic in the second instance, are those that act as intestinal antiseptics, and many times apparently a course of chorea may be shortened with salicylates as well as with arsenic, and with much greater safety.

The seriousness of chorea in its ability to injure and change the mental health of the child, even perhaps impairing its future, should cause parents and physicians to be ever on the alert to forestall the incidence of the condition. All brain tire should be prevented, and the moment that a child is found not to sleep well, not to eat well, and to become pale should be the moment that rest and proper treatment is inaugurated.

The severe form of chorea, so-called chorea major, in which the movements are so constant as to exhaust the patient and to cause death, is probably due to septic conditions and malignant endocarditis. Fortunately this form of chorea is rare. The child must be given rest, even if it requires very large doses of chloral, and the other treatment is that of septic poisoning. The blood should be examined for bacteria, and if possible the proper antitoxin administered.

PULMONARY TUBERCULOSIS

In spite of all that has been said on the subject of diagnosing and treating this disease in its incipiency, the statistics of sanatoria for tuberculosis, and the continued frequency with which patients, who have been neglected, come to the lung specialist, call for continued comment and discussion.

Not more than one-third, and often less than one-fourth, of patients received at sanatoria have the disease in its incipiency. This is statistical proof of either a lack of diagnosis or the desire of physicians to make the attempt to cure patients outside of an institution. As most of these institutions are charitable, and therefore are expected to treat and care for patients only who need charity, the hardship on the physician from sending a patient to an institution, as soon as he discovers that the patient has the disease, cannot be great.

It is not the purpose of this article to urge that a patient be sent to an institution who can pay his physician for his services, who can be at rest more or less constantly in the open air in a location removed from a city's dust and smoke, who can receive the proper kind of food, and who will not be fretted by household worries and ill-judged and tiresome visits from friends. It is the object of this article to urge that when all these advantages cannot be offered a patient, he be sent to an institution equipped and properly located for the treatment of this disease, and be sent to such an institution before his lungs have become seriously affected.

The advantages of a sanatorium in the treatment of this disease, from the standpoint of rest alone, are just as great as are the "rest" advantages in a sanatorium for the treatment of neurasthenia.

When 50 per cent. of all patients received at the best sanatoria, even including those in the more advanced stages, have the disease arrested and are able to return to their occupations and usual life, and when from 75 to 80 per cent. of incipient pulmonary tuberculosis patients are able to leave institutions with the disease arrested and able to work, there can be little excuse for not sending patients with incipient tuberculosis to sanatoria.

No one will assert but that a certain number of these patients will have a recurrence of the disease, but the fact that the disease is arrested at all in such a large number of patients, when properly treated in sanatoria, is little less than miraculous when the disease is viewed from the standpoint of even twenty-five years ago.

It is not necessary to enumerate the early signs and symptoms of pulmonary tuberculosis, but a few suggestions expressed by Dr. Henry F. Stoll, of Hartford, Conn. (*Yale Medical Journal,* March, 1909) will be of value.

A patient who shows debility, unless a satisfactory diagnosis of the cause is immediately made, should not be dismissed without a thorough physical examination, which, as Stoll says, will take at least from 30 to 45 minutes. If such a patient comes during a busy office hour, a special appointment should be made for him.

Stoll reminds us that:

"1. Patients with incipient tuberculosis do not usually look ill.

"2. A complete history is often of more value than a physical examination.

"3. The absence of physical signs and the failure to find tubercle bacilli in the sputum do not in themselves exclude tuberculosis.

"4. Pulmonary hemorrhage in a young adult, even without symptoms or physical signs, and with normal temperature and pulse, should always be considered to be due to tuberculosis, until it can be proved to be due to some other cause."

Many times the tuberculin skin test will clear up an otherwise doubtful case.

New and Nonofficial Remedies

Since the publication of the book "New and Nonofficial Remedies, 1909," the following articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections to aid in the revision of the matter before publication in the book are asked for.

The Council desires physicians to understand that the acceptance of an article does not necessarily mean recommendation, but that so far as known it complies with the rules adopted by the Council.

W. A. PUCKNER, Secretary.

DIGITALEIN CRUDE.—Digitaleinum Crudum.—Digitalein crude is a mixture of glucosides from digitalis purpurea prepared according to the process of Schmiedeberg, containing digitoxin, digitalin and digitalein.

Commercial digitalein is an amorphous, yellowish-white, bitter powder, soluble ir lcohol, insoluble in chloroform and ether. foams on shaking. The solution yields a of lead acetate, ammonia water or tannic acid.

Actions and Uses.—Digitalein acts on the heart like digitalis. It is a diuretic.

Its uses are the same as those of digitalis.

Dosage.—0.001 to 0.002 Gm. (1/60 to 1/30 grain) two or three times a day.

SUPRARENALIN.—(See N. N. R., 1909.)

Suprarenalin Inhalant.—A 1:1000 solution of suprarenalin in an aromatized oil, containing approximately 10 per cent. of alcohol. Manufactured by Armour & Co., Chicago.

BILE SALTS—(See N. N. R., 1909.)

Proprietary Preparations:

BILEIN—Sodii glyco-taurocholas bovis—Abbott.—Bilein is a name given to a mixture of the essential salts of the bile.

Actions, Uses and Dosage.—See Bile Salts, N. N. R., 1909.

Manufactured by the Abbott Alkaloidal Co., Chicago. U. S. Trademark No. 44,140.

Bilein Pills, 1/4 grain.—Each pill contains bilein 0.015 Gm. (1/4 grain).

Bilein Pills, 1/8 grain.—Each pill contains bilein 0.008 Gm. (1/8 grain).

Bilein Pills, 1/12 grain.—Each pill contains bilein 0.006 Gm. (1/12 grain).

Prepared by Abbott Alkaloidal Co., Chicago.

IODONE OIL—Oleum Iodoni.—Iodone oil is a 2 per cent. solution of iodone crystals (See Iodone Surgical Dressing and Dusting Powder) in a mixture of alcohol, castor oil, and cotton seed oil. It is said to yield about 1 per cent. of iodine, slowly liberated on prolonged contact with moisture and to contain about 20 per cent. alcohol.

Iodone oil is prepared by dissolving iodone crystals in the mixture of alcohol and oils to which sufficient iodine has been added to overcome the decomposing effects of the solvent on iodone.

It is a clear dark reddish-brown oily liquid, having a specific gravity of about 0.912 at 25° C. (78° F.) and a faint alcohol-like odor.

When shaken with chloroform and water the chloroform acquires a violet color, which is decolorized by shaking with a solution of sodium thiosulphate.

If 5 Cc. of the oil is dissolved in 15 Cc. of chloroform and treated as under iodone ointment, considerable time being allowed during the titration for the complete liberation of the iodine (at least twenty-four hours), about 1 per cent. iodine, calculated from the volume of volumetric sodium thiosulphate solution, should be indicated.

Actions and Uses.—Iodone oil has the germicidal and alterative actions due to the iodine which is liberated on contact with moisture.

It is said to be useful in all catarrhal affections of mucous membranes, hay fever, etc.

Dosage.—Its employment should be regulated on the basis of its liberating 1 per cent. of iodine on contact with moisture. It may be applied as a spray or on pledgets of cotton or tampons. It can be injected hypodermically into tuberculous joints, etc.

Manufactured by the Henry C. Blair Co., Philadelphia, Pa. No patents or trademarks.

IODONE OINTMENT—Unguentum Iodoni.—Iodone ointment is a mixture of iodone crystals with petrolatum, said to contain about 4 per cent. of iodone and to yield about 2 per cent. of available iodine slowly liberated on contact with moisture.

Iodone ointment is a dark green unctuous mass, having the consistency of petrolatum and a faint iodine-like odor.

A small amount dissolved in chloroform in a test tube and shaken with water should impart to the chloroform a violet color, which is destroyed by addition of sodium thiosulphate solution.

If 2 to 3 Gm. of iodone ointment is weighed and dissolved in 15 Cc. of chloroform; 30 Cc. of water added and shaken frequently during one hour; the mixture titrated with tenth-normal sodium thiosulphate solution using starch as indicator, not less than 2 per cent. of iodine should be indicated.

Actions and Uses.—Iodone ointment has germicidal, alterative and stimulant powers due to the iodine liberated.

It is said to be useful in all conditions in which the local use of iodine in ointment form is indicated.

Dosage.—Its employment should be regulated on the basis of the liberation of 2 per cent. of available iodine on contact with moisture.

Manufactured by the Henry C. Blair Co., Philadelphia, Pa. No patents or trademarks.

BISMUTH BETA-NAPHTHOLATE — Bismuthi Beta-Naphtholas.—Bismuth beta-naphtholate is the bismuth salt of beta-naphthol.

Bismuth beta-naphtholate occurs in the form of a brownish or grayish powder without odor, almost tasteless and insoluble in water. It is slightly soluble in alcohol.

1 to 2 Gm. bismuth beta-naphtholate is shaken in a separator during one hour with 25 Cc. chlorform and 25 Cc. concentrated hydrochloric acid, and then 50 Cc. water added and again shaken. The chloroform solution drawn off and the acid mixture extracted with three more portions of 10 Cc. chloroform and the combined extracts evaporated and dried to constant weight over sulphuric acid, a residue should remain weighing at least 15 per cent. of the material used, and should respond to tests of identity for beta-naphthol.

The acid solution from which the naphthol has been extracted is transferred to a beaker, diluted to 200 Cc., heated to boiling, ammonia water added till turbidity appears, then sufficient hydrochloric acid to clear up the turbidity and then 50 Cc. of 10 per cent. ammonium phosphate solution is added to the boiling liquid. The precipitate is allowed to subside, the clear liquid decanted through a tared porcelain Gooch crucible, the precipitate washed with hot water by decantation and finally transferred completely to the crucible. The precipitate and crucible are dried, placed in a nickel crucible, and exposed to the full heat of a bunsen flame till the weig veight of the resulting bismuth phosphate hould yield a figure (representing bismuth, than 60 per cent. of the material taken.

1 to 2 Gm. bismuth beta-naphtholate is weighed to a small asbestos plugged percolating tube, 5 Cc. chloroform added, mixed by means of a glass rod, and allowed to percolate into a tared dish. When the liquid ceases to drop, a further portion of 5 Cc. of chloroform is poured into the percolator and also allowed to percolate into the tared dish. The stem of the percolator is washed with a little chloroform, and the combined washings and the percolates allowed to evaporate spontaneously and the residue brought to constant weight over sulphuric acid. The residue should not exceed 1 per cent. of the material taken.

Actions and Uses.—Bismuth beta-naphtholate is decomposed into its constituents in the intestines, where it exerts the effects of bismuth salts and of beta-naphthol. Hence it is used in catarrhal and fermentative gastroenteric disorders, such as gastritis, dysentery, diarrhea, etc.

Dosage.—For children 0.1 to 0.3 Gm. (1½ to 5 grains) and for adults 1.5 to 5 Gm. (22 to 75 grains) daily.

A mixture of beta-naphtholate with acacia should be avoided as a viscid precipitate rapidly becoming hard is likely to be formed.

Proprietary Preparation:

ORPHOL.—A name given to bismuth beta-naphtholate.

Manufactured by the Chemische Fabrik von Heyden, Radebuel near Dresden, Germany (Schering and Glatz, New York). U. S. patent No. 51635. U. S. trademark No. 27482.

Orphol Tablets.—Each tablet contains orphol, 0.3 Gm. (5 grains).

Non-Proprietary Preparation:

Bismuth Beta-Naphtholate.—P-W-R.

Manufactured by the Powers-Weightman-Rosengarten Co., Philadelphia.

ARTICLES ACCEPTED FOR N. N. R. APPENDIX

Manhattan Eye Salve Co., Owensboro, Ky.

Compound Yellow Oxide and Adrenalin Ointment (M. E. S. Co.)—An ointment said to contain yellow oxide of mercury 1 per cent., solution of adrenalin chloride 5 per cent., menthol 0.04 per cent., phenol 0.2 per cent., hydrous wool fat 25 per cent., white petrolatum sufficient to make 100 per cent.

Cocaine and Adrenalin Ointment (M. E. S. Co.)—An ointment said to contain cocaine hydrochloride 2 per cent., solution of adrenalin chloride 17 per cent., hydrous wool fat 25 per cent., white petrolatum sufficient to make 100 per cent.

SATURDAY, DECEMBER 18, 1909

AN ANTIVIVISECTION EXHIBITION

An antivivisection exhibition has been on view for two weeks at a busy point on Fifth Avenue, New York. Most of the exhibits belong to the American Antivivisection Society of Philadelphia. These exhibits were displayed in Philadelphia last spring and again at Atlantic City last summer. The American Antivivisection Society plans to make the show permanent and to send it extensively through the country (to Washington, Chicago, Los Angeles, and other cities) to "educate" people regarding the "horrors" of the laboratory use of animals. This program renders desirable a consideration of the features of the display and their significance.

The center of agitation in the exhibition is an array of animal holders. Various forms of this apparatus are displayed, some of them prominently in the front windows, to attract the attention of the passing crowd. There are six stuffed dogs, among them a lap-dog and other pets, fastened in distressful positions in the holders. An attendant informs the visitors that animals are thus fastened down in laboratories. She is careful to make no mention of anesthesia.

Any sympathy roused by the dead dogs in the holders is intensified by the paintings and prints on the walls, representing dogs fastened and gagged in various positions of torture. When an attendant was informed that one of the pictures could not possibly represent a conscious dog, since the dog, free to struggle, was evidently not struggling, she replied: "Doubtless the dog is curarized, and, though in great pain, is unable to move." When informed that the dog must be dead, because a curarized animal cannot breathe, and this animal was not receiving artificial respiration, she was without further resource.

An attendant, when asked why the head-holders were used, declared that their purpose was to break the jaws of the dogs. Why apparatus was used to break the jaws of dogs, she did not know.

Besides the dogs fastened in holders there is another dog, an attractive little terrier, stuffed in a sitting posture, with a tracheotomy wound in the neck, painted red. This dog is introduced as a victim of vivisection. None of the conditions of the operation could be learned. Probably, if the animal was operated on before death, it was completely anesthetized during the operation, and passed from anesthesia to its place in the exhibit, but the visitor is permitted to draw quite different inferences.

A stuffed fish resting on a board, a stuffed pigeon fastened to a support, an enormously overstuffed cat gagged and strapped to a holder, complete this "revelation" of methods of handling animals.

Near by, however, over a row of gas-burners, is an oven in which lies a stuffed rabbit, its mouth widely opened, as if gasping for its last breath. An attendant informs the visitor that this oven is used in laboratories to roast animals alive and, as they die, to study "nerve action and the circulation." The oven is an ordinary incinerator used in laboratories to burn waste and refuse!

The remaining features of the exhibit are on the walls. There are two entirely fanciful pictures of Pawlow dogs, representing them, quite falsely, as wasted, miserable creatures, sick unto death. There are eleven characteristically malicious and untruthful cartoons from *Life*. There is an enlarged illustration from Cyon's "Methodik" (Plate xv) showing a dissection of the salivary glands, and below it is stated: "This agonizing and hideous mutilation is performed without anesthetics," a falsehood. There is an oil painting of a rabbit stretched as if crucified, with a nail driven through each foot; from each wound blood is flowing, a picture to harrow the heart of the onlooker. What possible reference has this to any laboratory procedure? Another painting represents a dog strapped and gagged, but evidently struggling, while two men, armed with knives, gaze at the bloody gaping wound in its abdomen, with glee on their faces.

Such is the travesty on medical research presented to the public by the antivivisectionists. The untruth of the details has been stated, but the wickedly suggestive implications which make the very atmosphere of the display cannot be adequately described. The fundamental evil of the exhibition is the presentation of a false alternative. The picture of a dog bringing succor, and of another dog bound to a holder, entitled, "The Way They Treat Us" and "The Way We Treat Them," sums up the situation. If that were all, nobody would hesitate on which side to stand. It is no wonder that nearly fifty portraits of poets, novelists, statesmen, artists and clergymen, whose words express their objections to cruelty, have been collected to adorn the walls of this exhibition. Every decent man is opposed to cruelty. But that is not the question. It would be as fair to set up a picture of Grenfell stabbing his faithful dogs to death, labelled "Is This the Way to Treat Your Pets?" as it is to represent medical research as this grotesque show represents it. Grenfell killed his dogs to save his life, and every man with common sense commends his bravery, resourcefulness and proper sense of values.

The high purpose of medical research and its beneficent results for human welfare—the compelling motives of that investigation which utilizes animals, and the care taken for the comfort and health of the animals, in laboratories—these conditions, which alone give meaning and possibility to medical investigation, are kept carefully in the dark.

The visitors at the exhibition are mainly women, though many children, some quite young, have been seen gazing at the horrifying sights. The attendants are women—women who have never seen the inside of a laboratory of medical research, and who let their morbid imaginings take the place of facts. They move about among the visitors making insinuating remarks and stating falsehoods with an easy assumption of knowledge they have never possessed. They show an instrument-maker's catalogue to prove the truth of their representations—again with no mention of anesthetics. A catalogue of the instruments used in surgical operations on man could be used with the same sly suggestion of torture. As the visitors leave, the attendants hand them circulars containing garbled statements, misleading quotations, and reiterated falsehoods, the untruth of which has been often pointed out. Thus the exhibition is untrue in its representations, evil in its implications, and altogether harmful in its possible effects.

When the exhibition was at Atlantic City last summer the Philadelphia *Ledger* was moved to state editorially:

"It is really a serious concern that a number of good women, or others, should devote their labors to harrying the nerves of the crowd and inciting them to ignorant hostility against the humane studies which have done so much for the service of mankind. The public exhibition of an anatomic museum would be in any case an offense against taste and decorum; when it is employed for misrepresentation and obscurantism and for the propagation of false sentiment, prejudice and intolerance, it is proper to speak of it only with the most serious condemnation.

"Utterly preposterous as the 'chamber of horrors' on the Boardwalk must appear to all who *know* anything of the subject it pretends to illustrate, it yet has its serious aspect, as an attempt to play on ignorant emotion and to create a false sentiment in support of an unscientific, unreasonable, inhumane effort to impose indiscriminating and injurious restrictions on the acquisition of knowledge that is for the advantage of all living creatures."

When a lay paper takes such a stand as that, it is high time that members of the medical profession awaken to the harm that the opponents of research are doing. The public is being educated, but the ignorant are being led by the ignorant. If medical investigation is not to be seriously hampered in this country, those who do not know must be led by those who do, and must be taught to see the importance to the general welfare of the efforts which are being made in the medical laboratories, with the help of lower animals, to penetrate the mysteries of disease and death that confront mankind on every side.

THE BIOLOGIC RELATIONSHIPS OF THE BACTERIA

Discussions of the affinities of bacteria with other organisms, their phylogenetic relations to the higher plants and animals and the principles of classification within the group itself have often resulted in much uncertainty and difference of opinion. While it cannot be said that general agreement on these topics has yet been reached, there is no doubt that recent investigations into the physiology of bacteria have effectually disposed of some speculations once current. The position which bacteria occupy with reference to other groups of living organisms is to-day better defined than ever before.

The value of morphologic characters as a basis for determining bacterial relationships is evidently not so great as that of the physiologic manifestations of these organisms. This is so, not only because external structural characters are not easily studied in organisms that lie close on the borders of invisibility, but because internal—that is, physiologic or, perhaps more exactly, chemical—qualities are the more fundamental. The outer form is determined by the internal constitution and not the reverse. For these reasons some of the most recent attempts to classify bacteria and to establish their relationships to other forms of life have been based on physiologic grounds. Reference has already been made[1] to the excellent monograph of the Winslows on the classification of the micrococci. These authors essayed to bring order into the welter of genera, species and varieties that long existed in this important group of bacteria and they adopted for this purpose chiefly physiologic distinctions. The same principles have been more recently utilized by Jensen in his ambitious attempt to construct a "natural"—that is to say, genealogical—classification of bacteria.[2] Jensen very properly takes advantage of the significant discoveries of the last few years regarding the physiologic activities of certain bacteria. Three chief groups are distinguished:

1. Bacteria which are like the green plants in requiring neither organic carbon nor organic nitrogen. These are the so-called autotrophic bacteria, which possess the remarkable property of being able to build up both carbohydrates and protein out of carbon dioxid and inorganic salts.
2. Bacteria which need organic carbon compounds, but can dispense with organic nitrogen. These organisms can synthesize protein out of carbohydrates (or organic acids) and ammonia, nitrogen or nitrates.
3. Bacteria which are like the animals in requiring both organic carbon and organic nitrogen compounds. This group cannot bring about either protein or carbohydrate synthesis out of inorganic substances.

These fundamental subdivisions serve to illustrate the method followed by Jensen in drawing up his outline of a natural system of bacterial classification. It is sufficient to say that the other groupings suggested by this author are equally logical and are based on recent physiologic studies. Some conclusions of general interest may be noted. The mode of nutrition of the first-mentioned—autotrophic—group of bacteria points to them as being in all probability the first living organisms to appear on the earth's surface. Both plants and animals originated from such a parent stock, Jensen's opinion being that the animals—flagellates—were first to appear. At all events, bacteria probably gave rise, on the one side, to the protozoa, on the other to the blue-green algæ.

---

[1] The Classification of Bacteria, THE JOURNAL A. M. A., Jan. 23, 1909, lii, 309.

[2] Jensen: Centralbl. f. Bakteriol., II., 1909, xxii, 305.

The nutritional requirements of the second and third groups, as above specified, indicate that these bacteria are phylogenetically younger than the first group. By the same mode of reasoning, the carbohydrate-fermenting organisms are older than the typical bacteria of nitrogenous putrefaction, and, to carry it still further, the lactose-fermenting varieties are of more recent origin than those related varieties which are not able to attack this carbohydrate, since lactose became available as a food-substance only with the relatively late advent of mammals. Again, the gelatin-liquefying species have developed, as a rule, out of the related non-liquefying species, since protein decomposition, which is itself one of the later acquisitions of micro-organisms, is facilitated by the secretion of proteolytic enzymes. The parasitic bacteria are naturally of more recent origin than the related saprophytic forms. Jensen finally constructs a very interesting genealogical tree which makes plain the relationships of the bacteria to the *Protozoa* and the *Cyanophyceæ* (blue-green algæ), shows a possible connection through the *Actinomycetes* with the *Eumycetes* (molds), and gives also a good conception of the physiologic relations between existing groups of bacteria.

Any attempt to bring the hazy realm of micro-organic life into orderly relation with the better-known macroscopic living world must be welcomed. Jensen's very interesting and ingenious effort has a value, possibly only provisional, but not to be overlooked for the present.

OLD MEXICAN MEDICINE

American historians, especially W. H. Prescott and H. H. Bancroft, have called attention to the fact that medicine reached a very high development among the Mexicans before the coming of Cortés. Their hospitals were well arranged, numerous, and existed in nearly every part of the country; and the traditions of treatment and the observations made on patients raised the art of healing to a high plane. The knowledge of plants was extensive, and even the science of diagnosis was notably developed. Women as well as men practiced medicine, and the department of women's diseases was exclusively in their hands. Indeed, medical traditions were so advanced as to make students of the history of medicine doubt whether such a high development of medical art and science could have been attained among a people apart from the great stream of medical tradition in Europe. There are records of cases in which European physicians failed and Mexican practitioners were successful. Cortés and his men were so well treated, both for wounds and for ailments of various kinds, that the former is said to have asked the Spanish government not to allow physicians of the Old World to come to Mexico.

A recent work by A. Gerste[1] on the medicine and botany of the ancient Mexicans gives very interesting information on this subject. The profession of medicine in Mexico, as in other countries—notably Ireland—was a family inheritance; and the secret medical formulas used by the Aztecs were transmitted from father to son. Their remedies were mainly herbal and of many different classes—antidotes, diuretics, depuratives, emetics, emollients, febrifuges, laxatives, purgatives and vermifuges. The seeds of a certain plant, not now to be readily identified, were used to make an intoxicating liquor that was given for anesthetic purposes to patients on whom an operation was about to be performed. Sahagun describes a solution which the Mexicans applied to wounds to make them heal rapidly and smoothly, and which, in Gerste's opinion, had the effect of an antiseptic. The Mexicans used a number of means to arrest hemorrhage, among them a stone applied to the back of the neck to stop bleeding of the nose. They used their remedies in many forms, as decoctions, infusions, oils, unguents and plasters; and certain gums and resins were used as electuaries. Hydrotherapy was considerably resorted to, and vapor baths were commonly employed.

As a consequence of the interest of the Aztecs in medical botany, botanical science was much farther advanced among them than might be expected. Gerste does not hesitate to say that their botanical knowledge was far ahead of that of the European world of their time. Their classification of plants was superior to that in use in Europe. Several centuries before the genius of Linnæus substituted for long descriptive terms the concise designation by means of a generic name and a specific epithet, the Aztecs had a botanical nomenclature resembling this in some particulars and distinctly superior to that of contemporary Europe. Besides they laid the foundation of geographic botany which is usually supposed to be of much more recent origin and traced the influence of temperature and elevation on plants in a scientific way. Their knowledge was imperfect, but showed many signs of fine powers of observation and abundant research.

The Duc de Loubat, at whose expense these notes have been published in their present form, has placed

---

1. Gerste, A.: Notes sur la médecine et la botanique des anciens Mexicains, Rome, Imprimerie Polyglotte, Vatican, 1909.

the world of letters under renewed obligations, for in recent years he has shown himself an intelligent and beneficent patron of history and literature by the republication of many important documents relating to America.

THE PRESENT STATUS OF THE ARMY MEDICAL CORPS

But a few years ago the matter of maintaining the personnel of the Medical Corps of the Army at the authorized quota was a subject of grave concern to the Surgeon-General's office. Numerically, the corps, as authorized by Congress, only distantly approached the real needs of the service, and the slow influx of young men was such that the vacancies annually occurring were by no means filled by the applicants accepted at the annual examinations. For instance in the year 1907 there were sixty-four applicants, of whom ten were accepted for the Army Medical School in October, and subsequently commissioned as first lieutenants in June, 1908. The vacancies occurring from October, 1906, to October, 1907, totaled eleven. It is thus seen that the vacancies naturally occurring exceeded the new admissions to the corps during that year. In May, 1908, an examination of fifty-eight candidates gave nine qualified men. In August, 1908, four months after the passage of the reorganization bill, the figures became one hundred and twenty-eight for applicants and twenty-five for accepted candidates. There had been but a brief season in which to bring before the medical profession of the country the greatly increased advantages carried with a commission in the Medical Corps by virtue of the act passed last year, which reorganized the body and provided substantial increases in pay and promotion. In the period between October, 1908, and the same month of this year, the knowledge of the signal improvement worked by the new legislation was more widely diffused and the result is striking. The change is manifest in the number of applicants and accepted candidates, and when the later figures are compared with those of previous years it is evident that the recruitment of the corps is vigorously healthy. The records show that in January and July, 1909, two hundred and seventy candidates were examined and fifty-seven accepted, and the attendance at the Army Medical School in Washington this year is fifty-eight as compared to ten in 1907 and thirty-three in 1908.

Evidently there has been an awakening among the young medical men to a better understanding of the desirable features of an army medical officer's career. Pay and promotion are now on such a scale as to justify any young physician in considering the career, and in recent years resignation after admission is almost unknown, which shows that, when once identified, practically all are willing to remain.

There is now opportunity for scientific work and it is possible for any member of the corps, who has the necessary capabilities, to rise to the plane of Sternberg, Reed, Carroll, Gorgas and many others in the field of preventive medicine, and every incentive is given the internist, surgeon and bacteriologist in his chosen work.

The Army Medical Corps was never so full of promise to young men, and appreciation of its great opportunities was never so manifest as at this time. A significant feature of the situation at present is the fact that so many applicants are drawn from the staffs of the larger hospitals in the country. The course of instruction at the Army Medical School, including, as it does, special training in bacteriology, sanitary chemistry, tropical medicine, military surgery and hygiene, supplies a post-graduate opportunity of exceptional character and the result has been one of great uplift in the professional equipment of the medical officer. The fact that the student officer is paid over $200 a month while in attendance at the school impresses one that the government is earnest in its effort to develop the Medical Department of the Army.

IMPURE DRINKING WATER ON LAKE VESSELS

The Public Health and Marine-Hospital Service for some time has made a study of the spread of typhoid fever by railroads and steamships. The opportunities for the investigation of typhoid dissemination by means of the railroads have not been good, but through the system of marine hospitals it has been possible for the service to study typhoid in certain of its relations to ships. These studies have shown that the typhoid rate is higher among sailors than among men of the same age-periods in the ports made by the sailors. In addition, there has occasionally been an opportunity of studying an epidemic of typhoid among a group of people who were passengers on shipboard at the time of probable infection.

As there have been found good reasons for believing that ships were in some measure spreaders of typhoid among their crews and passengers, it is evident that there is some hygienic error on ships, either in construction or custom, or both. The very palpable errors in both construction and custom are set forth in Dr. Cobb's article in this issue on "Water Contamination Aboard Ship and Its Prevention."

Properly kept storage tanks for drinking water are not an unreasonable requirement, and can be demanded under present powers of the Department of Commerce and Labor. This should and must be done.

In addition to the large number of men who constitute the crews, there are the great multitudes who are passengers whose rights and interests must be conserved. Boats which ply on polluted streams should be compelled to use distilled water; those which ply on fresh water lakes would find it preferable to fill their tanks by special tubes after the ship has gone far enough from shore to secure pure water. Obviously ships plying fresh waters must be made by government to change their drinking-water methods. Polluted fresh water is no more fit to be sucked up through sea-cocks for drinking purposes than is salt water.

There is another phase of the relation of ships to the spread of typhoid which is even more important than that investigated by Dr. Cobb, and that is the disposal of sewage by the ship. At some lake ports it is possible for boats to pour out feces and slops right over the intake of the city's water supply. The psychology of approaching disembarkation crowds the toilet rooms just as the boat is passing the cribs. A large volume of excreta is deposited in the water near the intake. The cure for this situation may lie along any one of three lines: 1. Passenger vessels can require that all toilet rooms be kept locked in certain locations—to be determined in each case. This is the custom at present in vogue on the railroads, and has the advantage of having had its feasibility demonstrated. 2. Ships could be built with holding tanks for slops and sewage—these to be discharged after the ship is well away from intakes. This method would cause less inconvenience to the passengers and is, of course, preferable. 3. The third plan is that suggested by Surgeon Young and Major Judson,[1] namely, to designate certain areas about the cribs as quarantine anchorages which must be avoided by shipping.

The very necessary measures for the control of this noxious situation could easily be interpreted to rest with the Department of Commerce and Labor, the Treasury Department or the War Department. Different bureaus in the first two that might easily find legal warrant for control are those of navigation or the Public Health and Marine-Hospital Service. At any rate, all will agree that the situation demands prompt and effective action by some live government official.

A PLAGUE FOCUS IN CALIFORNIA

Plague foci, permanent in character, have been recognized for years as existing in China, northern India and South Africa. There seems little doubt that another such menacing center of fixed character has developed in California, thus making the fourth of the world's plague foci. In all these foci, or plague centers, the disease is kept in existence through rodents of one variety or another, is mildly epizootic in character and only rarely, under ordinary circumstances, is conveyed to human beings. But it is now thoroughly proved that from these permanent incubation districts the disease is conveyed to man through the intermediary, first of the rat and then of the flea. The reports on plague in California published in THE JOURNAL[2] over a year ago strongly hinted at the fact that a well-distributed infection of ground-squirrels probably existed; the recent work of the United States Public Health and Marine-Hospital Service in charge of Passed Assistant Surgeon W. Colby Rucker, and described by the latter in THE JOURNAL[3] last week, leaves no room for doubt. The work was in an entirely new field of preventive medicine and has been done against the great physical odds of long distances, wild country and burning summer heat; yet in spite of this the reports already presented show that Dr. Rucker has reduced what was formerly only a brilliant hypothesis to a certainty demonstrated in its smallest detail. Plague-infected squirrels have now been found in Contra Costa, Alameda, Santa Clara, San Benito, Santa Cruz, San Joaquin, Stanislaus, Merced and Santa Barbara counties—an area of about five thousand square miles. The eradication of squirrel plague by the extermination of ground-squirrels in such an enormous area is a task so stupendous as to be apparently impossible. Nor is the existence of plague in squirrels without menace to the human inhabitants of the infected area. Within the last few months three cases of human plague have occurred in Alameda County, and in each instance it has been proved that the disease was received from ground-squirrels. In twelve counties of the state, scouting parties are at work, the present object of the United States Public Health and Marine-Hospital Service being to determine, if possible, the extent of the territory infected; in all of this work the California State Board of Health is actively cooperating. It seems hardly necessary to call attention to the very grave menace to the entire country in the existence of this plague focus; it is not a mere local danger, but a national one. It is undoubtedly true that a severe epidemic of human plague could scarcely occur in a vermin-free population; but it is equally true that the infection may be conveyed at any time to any part of the United States, and in very densely populated centers the people are not always vermin-free. The existing facts present a problem both large and of grave import.

THE CURE-ALL IN ANCIENT ERIN

In the little volume on "The Antient Medicine of Erin," issued by Burroughs, Wellcome and Company, there is a paragraph on the announcement of a remedy in Ireland, about a thousand years ago, which ought to make the advertising managers of the nostrums of to-day feel that they are the feeble offspring of a degenerate age. This ancient Hibernian cure-all was claimed to be a preservative from death, a restorative for the living, a compensation for the want of sinews, a remedy for the tongue-tied (under which term were included all those suffering from defects of speech, from true aphasia to stuttering), a cure for swelling in the head, for wounds by iron, or of burning by fire or of the bite of the hound. It further prevented "the lassitude of old age, cured the decline" (by which the Irish have always designated consumption), the rupture of the blood-vessels (mentioned immediately after consumption because of the tendency to hemorrhage), took away "the virulence of the festering sore and the fever of the blood and even the poignancy of grief." The promise was that "he to whom it shall be applied shall be made whole"; and the announcement concludes: "Extolled be the elixir of life, bequeathed by Diancecht to the people, by which everything to which it is applied is made whole." In comprehensiveness of claims, that certainly leaves little room for improvement. We wonder if some of the credulous in those days did not try the stuff on leaky roofs and ragged clothes.

Medical News

COLORADO

Tag Day in Denver.—The Hospital Saturday and Sunday Tay Day in Denver netted $5,000.

Personal.—Dr. John H. Larson has succeeded Dr. Joseph W. Gothard, resigned, as health officer of Palisades.——Dr. Charles E. Holden, Longmont, is reported to be seriously ill in Orange, Cal.

New Dormitories for State Hospital.—The State Hospital for Insane, Pueblo, is to have three new dormitories, each of which will have accommodation for 75 patients. Two of these buildings will be for women and one for men, and they will cost $50,000 each.

State Antituberculosis Association Formed.—The Colorado Association for the Prevention and Cure of Tuberculosis has recently been organized with headquarters in the Capitol Building, Denver. The organization will endeavor to have tuberculous persons registered, and will teach means of prevention of tuberculosis by continual agitation through the press and through lectures to the public. A tuberculosis exhibit, which has been held for two weeks in Denver, has recently closed.

ILLINOIS

Medical Staff Elects Officers.—The medical staff of the Graham Hospital, Canton, has organized with the following officers: President, Dr. Willis T. Zeigler; vice-president, Dr. Martha A. Richardson, and secretary, Dr. James E. Colman.

Asks for Larger Hospital.—President Busse of the board of commissioners of Cook county, in his annual report, points out the urgent need of a larger hospital. The present hospital, with a capacity of 1,300 patients, has cared for 1,700, the daily average for the year being 1,451. The new hospital should be large enough to accommodate 2,500 patients.

Victory for Pure Food.—Judge J. Otis Humphrey of the federal court, on December 10, is said to have decided that fifty cases of preserved eggs, shipped by the W. H. Hippolite Company, St. Louis, and seized in Peoria last March by government inspectors, were injurious to health and that the seizure was justified. Attorneys for the defense filed an appeal to the United State Appellate Court. Dr. Harvey W. Wiley, Washington, D. C., testified that two pounds of boric acid were used for one hundred eggs.

Personal.—Dr. August F. Bechtold, New Athens, who has been ill with tetanus in St. Elizabeth's Hospital, Belleville, is reported to be out of danger.——Dr. Charles B. Fry, Mattoon, before leaving for Biloxi, Miss., was presented with a diamond stud and Elk charm by the local employees of the Illinois Central Railroad.——Dr. William L. Secor and family, LaGrange, left for Florida December 6, where they will spend the winter. Dr. Secor has been made physician-in-chief of the new Ponce de Leon Sanitarium, St. Petersburg.——Dr. Jesse D. Dickinson, Galva, underwent a second operation at Cottage Hospital, Galesburg, November 22.

District Society Meeting.—The thirty-sixth annual meeting of the North Central Illinois Medical Association was held in Streator, December 7 and 8, and the following officers were elected: President, Dr. Franklin A. Turner, Sandwich; vice-presidents, Drs. Alfred E. Owens, Princeton, and Thomas W. Burrows, Ottawa; secretary-treasurer, Dr. George A. Dicus, Streator (reelected), and censors, Drs. John C. White, Seatonville, Charles A. E. LeSage, Dixon, Joseph I. Knoblauch, Metamora, John M. Kaiser, Somonauk, and Alonzo B. Middleton, Pontiac. Life memberships were conferred on Drs. Charles E. Cook, Mendota, Alfred E. Owens, Princeton, Thomas H. Stetler, Paw Paw, and Benjamin F. Landis, Tiskilwa.

Chicago

Sanatorium for Tuberculous Chicagoans.—A number of Chicago physicians and citizens have inaugurated a movement to purchase the Valmore Ranch near Las Vegas, N. M., and establish a tuberculosis sanatorium for patients of moderate means who may be able to do some work and will be paid for that work. Dr. E. Fletcher Ingals is at the head of the organization and a considerable amount has already been promised for the enterprise.

The Fenger Memorial.—The directors of the Fenger Memorial Association have decided to set aside $400 for 1910 to aid in medical investigation. Application with necessary details should be sent to the secretary, Dr. Ludvig Hektoen, 1743 West Harrison street, not later than February 1, 1910. This appropriation is part of the income of the Fenger Memorial Fund, which was created by subscriptions in honor of Dr. Christian Fenger of Chicago, who died in 1902, and the income is used to further medical investigation.

KENTUCKY

Tuberculin Test for Cattle.—The executive committee of the State Board of Health, meeting with the government experts, who have been making tuberculin tests of the cattle of Kentucky, announces that of 1,703 cattle subjected to the tuberculin test, 16 per cent. were found to be diseased.

City Hospital Condemned.—The November grand jury of Jefferson county considers the management of the county institutions creditable. Praises are given the Blind Asylum and the Lakeland State Hospital; the County Poor House was condemned as unfit to harbor the two dozen inmates; the bakery, dairy, and dining room of the Home for the Aged and Infirm were condemned, and the following report was made on the Louisville City Hospital:

> It is perhaps superfluous to say that this condition is a hundredfold worse at the City Hospital. The venerable building, crumbling to decay, after serving to shelter three generations of the city's sick disabled and unfortunate, is kept as clean as possible, and its inmates cared for with as much comfort as the building will permit. The development of modern hospital design and practice has left Louisville's facilities so far in the lurch that the institution has become a reproach and a disg[illegible] That it makes better provisions for its mal[illegible] for the poor unfortunates huddled in its [illegible] espeaks not a city of progress, as its great seal proudly boasts, but marks Louisville in this respect which should be its chief concern, as the city that has stood still. Efforts to remodel and renovate a hospital which has been in use nearly three-quarters of a century would be as impossible as they would be absurd. Entire replacement of the buildings is imperative, and further postponement of this drastic remedy will be a disgrace to the community.

The mayor of the city has stated that he favors the construction of a new city hospital to cost a million dollars and will urge the voters to endorse the proposition before the next legislature.

MARYLAND

Hospital Organized.—At a meeting held in South Baltimore, presided over by the mayor of the city, with Dr. John R. Abercrombie as secretary, the South Baltimore Hospital was organized and many contributions were received.

Advocates Inspection of Meats.—At a conference, held in Hagerstown Dec. 9, by county health officers and others for the consideration of a state law for the inspection of meat, Dr. Marshall L. Price, Baltimore, secretary of the State Board of Health, presented the draft of a bill, which was held to be too stringent. He was asked to modify and present it again. All present favored the creation of the office of state meat inspector.

MASSACHUSETTS

Sentenced for Manslaughter.—Frank L. Hill, an "herb doctor" of Fall River, who pleaded guilty to manslaughter in connection with the death of Amelie St. John of Woonsocket, R. I., is said to have been sentenced on Nov. 17 to imprisonment for not less than seven or more than ten years in the state's prison.

More Land for Hospital.—The trustees of the Boston State Hospital, with the approval of the governor and council, have purchased a site on Fenwood Road, containing about 90,000 square feet, near the Harvard Medical School, on which a hospital will be erected for the first care and observation of mental patients and the study and clinical treatment of mental diseases.

Personal.—Dr. Myles Standish, Boston, has been appointed Williams professor of ophthalmology in Harvard Medical School.——Dr. George L. Richards has been elected president of the Fall River Antituberculosis Society, and Drs. Joseph A. Barre and Henry A. Rosa, Fall River, and Edward W. Burt, Westport, directors.——Dr. Carl E. Meyer, Chicopee, has been appointed a medical inspector of schools.——Dr. Walter Channing has been elected a vice-president of the Brookline Antituberculosis Society.——Dr. John A. Gordon, Quincy, has been appointed vice-president of the Antituberculosis committee of Quincy, and Drs. T. Ramon Burke, Nathaniel S. Hunting, Willis J. Middleton, Daniel B. Reardon, and John T. Reynolds have been elected members of the board of directors.

NEW YORK

Hospital Site for Buffalo.—Mayor J. N. Adam announced at a meeting of the Tuberculosis Hospital Commission that he intends to buy the Perryville site for the hospital. This site includes 293 acres and the price is $19,650.

County Tuberculosis Hospitals.—Ulster County plans to take over the day and night camp for consumptives established last summer by the local committee on tuberculosis of the State Charities Aid Association and to convert it into a permanent hospital. Similar action has been taken recently by the counties of Monroe, Ontario and Schenectady. Like action is expected soon by the supervisors in some twenty other counties.

State Board Seeks to Prevent Blindness.—A special committee of the New York Association for the Blind which was appointed to investigate the causes of preventable blindness and to cooperate with physicians in seeking measures of prevention, reports that the committee has found that about one-*half of all blindness is due to preventable causes* and about one-third of the blindness of children is caused by ophthalmia neonatorum. This committee has united with the State Commisioner of Health in enforcing the use of a 1 per cent. solution of silver nitrate. The State Commissioner of Health will endeavor to provide this solution through local health officers to any physician or midwife applying for it. It has been enacted that birth certificates be returned within thirty-six hours instead of ten days as hithertofore.

New York City

Personal.—Dr. and Mrs. Alexander McLane Hamilton sailed for Europe on December 8.——Dr. Daisy M. Orleman Robinson has been elected a member of the *Société française de dermatologie et de syphiligraphie.* Dr. Robinson is the first woman member of this society.——Dr. Walter H. Kerby has succeeded Dr. John P. Schneble as house surgeon of St. Mary's Hospital, Jamaica.

For Cancer Research.—George Crocker, who died on December 4, left property valued at about $1,500,000 to Columbia University, the proceeds of the sale of said property to be used in the prosecution of researches as to the cause, prevention and cure of cancer, and in case the progress of science should at any time make such researches no longer necessary, the fund to be applied to other researches in medicine and surgery as may be determined by the trustees. The fund is at no time to be used for the erection of a building; hence the acquisition of this fund will lay on Columbia University the responsibility of providing a suitable building for this kind of work.

New Hospitals.—Work will soon be begun on the new Bradford Street Hospital which has just received an appropriation of $77,000 from the city. This institution will take the place of a reception hospital and will relieve the Kings County Hospital, which is overcrowded. The entire cost of the building will be $350,000, and it is intended that it will serve as a model in erecting other city hospitals.——The Staten Island Tuberculosis Hospital was already in great part completed when the city gave an appropriation of $1,350,000 recently. One million dollars had already been appropriated. The building can now be completed and will furnish accommodations for one thousand patients.

Buffalo

Personal.—Dr. Joseph Burke has been appointed surgeon of the Sisters Hospital.——Dr. Marshall Clinton has succeeded Dr. William Phelps as attending surgeon at the Buffalo General Hospital.

New County Hospital.—The board of supervisors of Erie county have appropriated $500,000 for the erection of a new county hospital. Further effort is being made for an appropriation of $200,000 for a building for the segregation and treatment of advanced cases of tuberculosis.

Municipal Tuberculosis Hospital.—The Municipal Hospital Commission has selected a site for the hospital at Perrysburg, at an elevation of 1,500 feet. The cost of the site is $19,200, and Mayor Adam has announced that he will pay for it and present it to the city. The hospital will be named the Adam Memorial Hospital, and the buildings are expected to cost about $200,000.

OHIO

Personal.—Dr. Robert Ingraham has been elected a member of the board of education of Cincinnati.——Dr. Louis Schwab, mayor-elect of Cincinnati, has decided to continue to serve on the city hospital medical board until the first of the year.

The McDowell Centenary.—On December 9, under the auspices of the McDowell Medical Society, a banquet was given at the Hotel Alms in honor of the centenary of the first ovariotomy performed by Dr. Ephraim McDowell on Mrs. Crawford, in Danville, Ky., Dec. 9, 1809. More than 150 physicians, many from Kentucky and neighboring states, were present. Dr. Louis Schwab was toastmaster. Dr. S. Cary Swartsel responded to the toast, "Ephraim McDowell," and gave a history of the life of Dr. McDowell, stating that he was born in Virginia, Nov. 11, 1771; married a daughter of the governor of that state; moved to Kentucky, but returned to Virginia to study medicine, and later studied in Edinburgh under Dr. John Bell; located in Danville, Ky., in 1795, where the operation which made his name famous, was performed. The woman lived for 40 years after the operation. Dr. McDowell died at Danville in 1830. A high tribute was paid to Dr. McDowell's services to humanity and to the medical profession. Dr. Fayette Dunlap, Danville, Ky., responded to the toast, "Pioneer Days in the Blue Grass," Dr. Rufus B. Ball, Cincinnati, on "Ephraim McDowell's Influence on Ligatures in Abdominal Surgery," and Dr. John H. Landis, Cincinnati, on "Modern Medical Martyrs." Remarks were also made by Judge McDowell, grandson of Dr. McDowell, and by Dr. Powell, both of Danville, Ky.

PENNSYLVANIA

Medical Club Election.—At the annual meeting of the Oil City Medical Club, December 2, Dr. Fanny Davis was elected president; Dr. John L. Hadley, vice-president; Dr. Sylvester W. Sellew, secretary, and Dr. Frank B. Jackson, treasurer.

Personal.—Dr. Evelyn Dickinson has resigned as second assistant resident physician of the women's department of the Norristown State Hospital for the Insane.——Dr. Charles C. Eicher, McKees Rocks, has been elected president and Dr. J. Donald Iams, Sheridan, treasurer of the Chartiers Branch of the Allegheny County Medical Society, which is taking the postgraduate course suggested by the American Medical Association.

Work at State Tuberculosis Dispensaries.—The State Department of Health has now 114 tuberculosis dispensaries in the commonwealth, new ones having been recently opened at Nanticoke and Brownsville. At present more than 11,000 patients are being treated at these dispensaries. Trained nurses are visiting the homes of the patients, instructing them how to care for themselves, and the other members of the household how to guard against infection. For the month ending October 20, the nurses made 10,338 visits, and during the ten months ending October 20, 76,794 visits were made and 471 patients were discharged from the dispensaries with the disease arrested.

Medical Staff Election.—The Ohio Valley Hospital, McKee's Rocks, at its annual meeting, December 6, elected the following staff for the coming year: Surgery, Dr. Charles G. Eicher, McKees Rocks, chief of staff, and Drs. Joseph G. Steedle and George R. Wycoff, both of McKees Rocks; medicine, Drs. Albert H. Burket, McKees Rocks, R. Hanover, J. Donald Iams, Sheridan, and Dr. Charles B. Keebler, McKees Rocks; and assistants, Drs. J. W. Burkett and William C. Minnich, McKees Rocks; eye, ear, nose and throat, Dr. George W. Beane; genitourinary diseases, Dr. John A. Hawkins, Pittsburg; diseases of children, Dr. George S. Bubb; obstetrics, Dr. John A. Williams, Sheridanville, and neurology, Dr. Christopher C. Hersman, Pittsburg.

State Charity Organization Meeting.—The first Pennsylvania Conference of Charities and Correction was held in Harrisburg, December 6 and 7. Governor Stuart presided at the opening meeting and the address of welcome was delivered by Mayor E. S. Meals. Addresses were also made by F. H. Nibecker of Glen Mills, chairman of the committee on organization, and Francis J. Torrance of Pittsburg, president of the State Board of Charities. At the morning session, P. R. Lee, general secretary of the Philadelphia section for organized charity, spoke on "Needy Families, Their Care and Treatment by Organized Charity." Dr. E. R. Walters, director of Health and Charities of Pittsburg, spoke on "Public Treatment of Needy Families." Papers were also read by Dr. James M. Murdock of the State Institution for Feeble-Minded at Polk, Dr. Henry M. Weeks of the state institution at Spring City, Dr. Frank J. Woodbury of the State Board of Charities, Monsignor J. W. Turner of the Archdiocese of Philadelphia, Professor David Emmert, Huntingdon, and Mrs. J. L. Anderson, Pittsburg. On Wednesday a permanent state organization was formed.

Philadelphia

Charitable Bequests.—A provisional bequest from an estate, valued at $57,500, to the Home of the Merciful Saviour for Crippled Children, was contained in the will of the late Marie

A. Brolesky.——The will of the late Catherine Boyle bequeaths $5,000 to St. Mary's Hospital.

Councils Vote to Buy Poor House Site.—On December 8, the city councils voted to purchase the land between State Road and Holmesburg Avenue and the Delaware river, adjoining the House of Correction, as a site of the proposed new home for the city's indigent. The tract comprises about forty-seven acres and the price to be paid will be about $50,000.

Gift to Jefferson.—Mrs. Henry C. Chapman has presented to the Jefferson Medical College all the laboratory apparatus and equipment used there by her husband, the late Dr. Henry C. Chapman, who was professor of the institutes of medicine and medical jurisprudence in that institution for twenty-nine years. The gift is said to be worth more than $20,000.

Surgeon General in Philadelphia.—Brigadier General George H. Torney, Surgeon General U. S. Army, made a visit to Philadelphia December 6. He was the guest of honor at a dinner at the Union League Club, made an address before the Northwestern Medical Society on "The Experiences of a Doctor in the Army," and was given a reception at the Southern Club in the evening.

Library for Jefferson Alumni.—The College Library of the Jefferson Medical College has a good working library of over 4,000 volumes in the college building in use by the students of the Jefferson Medical College. The alumni of this institution are invited to use the library whenever they are in the city. The library is open practically from 9 in the morning until 5 in the afternoon. It will be found on the first floor of the college building, Tenth and Walnut streets.

Honor Memory of Daring Physician.—A memorial tablet to Dr. Francis Kinloch Huger, of the class of 1797 of the University of Pennsylvania, the work of Dr. R. Tait McKenzie, was unveiled Nov. 5 by Miss Elizabeth Huger, a great granddaughter of Dr. Huger. Dr. J. William White made the presentation speech, and the memorial was accepted on behalf of the university by Dr. Wharton Sinkler. The tablet commemorates the daring attempt of Dr. Huger to rescue Marquis de Lafayette from the fortress of Olmutz, Austria, in 1794.

Personal.—Dr. Guy Hinsdale sailed for Europe, December 11. ——Dr. John M. Swan has been elected associate professor of clinical medicine in the Medico-Chirurgical College.——Dr. Harry Hudson has been elected chief of the orthopedic department of Jefferson Hospital and associate in orthopedic surgery in Jefferson Medical College.——Dr. Joseph Evans has been appointed professor of clinical medicine and medical adviser of students in the University of Wisconsin, Madison.——Dr. J. Frank Meade sustained a loss of about $800 by fire November 16.

Jefferson Hospital Clinical Society.—At a meeting of members of the staff of Jefferson Hospital, December 8, plans were made to form a scientific society to be known as the Clinical Society of Jefferson Hospital. The aim of the society is to encourage members of the hospital staff in research work and the compilation of scientific papers. The society is to meet the fourth Friday night of each month and the meeting for organization will be held on Jan. 28, 1910. The subject for discussion for that time will be "Pulmonary Embolism Following Abdominal Operations."

Plans New Hospital.—Plans have been drawn by Henry L. Reinhold and Lynn H. Boyer for a new building for the Roosevelt Hospital, 710 North Fifth street, the present quarters being inadequate for the demands of the river front and factory territory tributary to it. The new building will be four stories in height, with a frontage of forty feet and a depth of 125 feet, and will accommodate 150 patients. At present, with but fifty beds, the hospital is constantly filled. Since obtaining its charter as a general hospital in 1905, more than 1,700 patients have been admitted to the house and 17,000 have been treated in the dispensary.

Associations Elect Officers.—The annual banquet of the Medical Examiners' Association of Philadelphia was held December 9. Dr. John G. Clark, the retiring president, was toastmaster, and the following officers were elected: President, Dr. Samuel G. Walker; vice-president, Dr. Samuel H. Brown; secretary, Dr. Norris S. McDowell, and treasurer, Dr. George D. Morton.——The West Philadelphia Medical Society held its annual meeting and banquet December 6. The following officers were elected: President, Dr. Sherman F. Gilpin; vice-president, Dr. Hiram L. Lutz; secretary, Dr. Henry G. Munson; financial secretary, Dr. William M. Miller; and treasurer, Dr. Edmund L. Graf.

Baby Alliance Plans Campaign.—The Baby Alliance was formed last May, under the auspices of the Department of Health and Charities, the Board of Education and civic associations of women. The object of this body is to educate mothers in the elementary laws of hygiene and to establish milk stations, providing pure milk. A committee of seven met in Director Neff's office in City Hall and heard a paper read by Dr. Frank N. Yeager, infant mortality specialist of the city. He showed by statistics gathered by himself that one-half of the infant deaths were of babies of less than one year and that these deaths might easily have been prevented by better knowledge on the part of mothers.

Jonnesco in Philadelphia.—Dr. Thomas Jonnesco, dean of the medical faculty of the University of Bucharest, Roumania, visited Philadelphia, December 13, 14 and 15. He demonstrated his method of spinal anesthesia at Dr. Charles S. Frazier's clinic at the Hospital of the University of Pennsylvania and also of the clinic of Dr. Edward Martin at the same institution. He also gave an illustrated lecture at the University Hospital. On Tuesday at 1 o'clock he outlined his method and gave a demonstration at Dr. E. E. Montgomery's at the Jefferson Hospital and on Wednesday he gave a lecture and demonstration at Dr. W. L. Rodman's clinic at the Medico-Chirurgical Hospital. A dinner was given in his honor by Dr. Charles S. Frazier on Tuesday evening.

WISCONSIN

Lay Medical Journal.—It is announced that Dr. Julia Riddle, Oshkosh, has been elected editor in chief of a new monthly publication to be known as *The Layman's Medical Journal*, having for its object the eradication of preventable diseases. The collaborators on the staff are Drs. Anna B. Corr, Juneau, M. Adeline Riddle, Oshkosh, Belle P. Nair, Fort Atkinson, Johanna M. Droppers, Milwaukee, and Evelyn C. Hoehne, Milwaukee.

Personal.—Dr. Mazyck P. Ravenel, professor of bacteriology in the University of Wisconsin, Madison, has been elected a director of the Madison Antituberculosis Society, and has been appointed official reporter for the International Medical Congress at Buenos Aires, Argentina, in May next, where he will have charge of the tuberculosis program.——Dr. Thomas C. Phillips, Milwaukee, has been made dean and professor of ophthalmology and otology in the Wisconsin College of Physicians and Surgeons.——Dr. Peter B. Stewart, Chetek, is convalescent after a severe attack of pneumonia.——Dr. Wilson H. Van Dusen, Lancaster, who has been ill for several weeks, slipped and fell on a sidewalk Nov. 26, breaking his right arm. ——Dr. Henry T. Brogan, West Allis, has been appointed physician of Milwaukee county.——Dr. L. Rock Sleyster, Appleton, has been appointed physician of the state penitentiary.——Dr. George E. Knauf, Sheboygan, has been elected physician of Sheboygan county.——Dr. Susan Jones, Racine, has been elected secretary of the local society for the prevention of tuberculosis.

GENERAL NEWS AND COMMENT

Society Meetings.—The Missouri and North Arkansas Railway Surgeons Association was organized at Leslie, Mo., Nov. 3, with the following officers: President, Dr. Cyrus F. Crosby, Heber, Ark.; vice-presidents, Drs. T. D. S. McCall, Neosho, Mo., Samuel C. Daniel, Marshall, Ark.; and H. L. White, Rondo, Ark.; secretary, Dr. J. Oliver Cotton, Leslie, Ark., and treasurer, Dr. Asbury J. Vance, Harrison, Ark.——The following officers have been elected by the New England Pediatric Society: President, Dr. Charles P. Putnam, Boston; vice-president, Dr. Philip S. Potter, North Adams, Mass.; secretary-treasurer, Dr. Fritz B. Talbot, Boston, and councilors, Drs. John L. Morse, Arthur H. Wentworth, and Henry I. Bowditch, all of Boston.

The Health of the Army.—The report of the Surgeon General of the Army for the fiscal year just closed shows the lowest ratio of sick admissions on record, 575.47 per 1,000. The constantly non-effective rate for the enlisted strength of the army was 42.68 per 1,000 as compared with 46.17 for 1907 and 49.79 for 1906. The total admission rate was 1188.03 as compared with 1218.26 for 1907 and 1706.33 for 1906. The deaths from all causes were 414, of which 235 were due to diseases, the death-rate being 3.48 per 1,000 as compared with 3.44 for the preceding year. The highest death rates were from tuberculosis, pneumonia, and typhoid fever. The antityphoid vaccination test in the hospital corps has been found so successful that the surgeon general recommends the extension of the vaccination to include volunteers from all organizations to be detailed for duty outside of the United States and among troops to be ordered for special practice or maneuvers. He recommends that a medical officer be attached to the Militia Division to assist in the organization of the medical department of the militia and that the state authorities be required to equip a field hospital with its ambulance company for each three regiments in addition to regimental medical service.

The Health of the Navy.—The annual report of the Surgeon General of the Navy shows the relation of the different causes of death in the Navy and Marine Corps for the past fiscal year. Drowning heads the list with 47 of the 305 deaths, tuberculosis comes next with 30, pneumonia follows with 24, heart disease with 21, and nephritis with 15. Of the 26,350 sick admissions, 3,015 were due to venereal diseases, 2,631 to tonsillitis, 2.319 to wounds, and 1,677 to suppurative skin diseases. The ratio of admissions and readmissions per 1,000 of the strength for the year was 611.05 as against 630.08 for the previous year, and 649.65 for the decade from 1897 to 1906. The cigarette-tobacco bag is suggested as possibly playing an important part in the transmission of mumps, as the invariable habit of those who use tobacco in this form is to close the sack by pulling the puckering string with the teeth; thus the user of the sack by touching the saliva-soaked bag string may infect himself. Mumps occupies seventh place in the sick admissions, with 1,392, exceeding even the rate for bronchial and rheumatic affections. The insufficiency of the medical force is shown by the fact that less than 248 medical officers are available for the care of the 52,913 officers and men of the Navy and Marine Corps, or 1 to 254. Discontinuance of fresh milk as a part of the Navy ration is recommended, and the use of the Elliott ear protector against injuries by gun-fire is also recommended. Mention is made of the fact that among candidates for enlistment from the northwest, or those born in or long residents of the extreme northwest, thyroid enlargement of varying degrees, is found. The proposal to accept unusual period of watches on deck and in engine rooms for officers on board ship, in lieu of the physical tests of walking and riding does not meet with the approvel of the surgeon general, who believes that such tests will be an index of the moral stamina rather than the physical fitness of the officer.

FOREIGN

Nobel Prize Goes to Kocher of Berne.—The prize for medical research was this year conferred on Theodor Kocher of Berne, where he has been professor of surgery since 1872. He was born at Berne, Aug. 25, 1841, and is thus 68 years old. His fame rests mainly on his research on the physiology and pathology of the thyroid gland, although he is eminent as a surgeon and his "Manual of Surgery" is a classic text-book. His discovery of the cachexia that follows total removal of the thyroid was announced in 1883, and his work on the thyroid and parathyroids has inspired an immense amount of research in all lands. Among his latest works are some on transplantation of the thyroid, the blood picture in exophthalmic goiter, cancer of the thyroid, curability of gastric cancer, hypophysic and other tumors, and means to prevent and cure cretinism.——The professor of chemistry at Leipsic, W. Ostwald, received the chemistry prize, while the physics prize was divided between Marconi of wireless telegraphy fame and F. Braun, professor of physics at Strasburg. Switzerland, Germany, Italy, Sweden and France are represented in the recipients of the five prizes this year. The prize in medicine has been awarded in turn during the nine years since the foundation of the Nobel prizes to von Behring, Ross, Finsen, Pawlow, Koch, Golgi and Ramon y Cajal, Laveran, Ehrlich and Metchnikoff, and, finally Kocher, thus honoring eight different countries. Germany has had three recipients; France and Russia both claim Metchnikoff.

LONDON LETTER

(From Our Regular Correspondent)

London, Dec. 4, 1909.

A Historical Room at a College Museum

A special room has been added to the museum of the Royal College of Surgeons containing various exhibits of historical interest. The exhibits form a most interesting collection and include the body of a woman embalmed by Dr. Cruikshank and William Hunter in 1775; the mummified body of a boy who died from plague in 1665, which was found in the crypt of St. Botolph's Old Church; the skin of the heads of three Macas Indians from Ecuador so preserved that while contracted to the size of a doll's head they yet retain the features of living individuals; a collection of boots, shoes and gloves worn by the Irish giant O'Brien; pieces of human skin found nailed to the doors of Worcester Cathedral and the churches of Hadstock and Copford in Essex; a chain and belt used for securing lunatics; a cast of the head of Deeming, the murderer who was hanged at Newgate in 1892; and an electrical machine used by a surgeon named Birch about 1775, with a manuscript by his sister describing the cures said to have been effected with the machine.

Sleeping Sickness in Uganda

An important paper has been communicated to the Royal Society, the joint work of Col. Sir David Bruce, Capt. A. E. Hamerton, Capt. H. R. Bateman and Capt. F. P. Mackie, who constituted the sleeping sickness commission of the society recently sent to Uganda to investigate. The policy during the last two years of clearing the shores and islands of Lake Victoria of their inhabitants has been carried out. No native has been allowed to live or work within two miles of the shore except at a few cleared landing places, and within the last few months all the islands in the lake have been emptied of their population. Until recently it was believed that the tsetse fly, which conveys the disease, retains its infectivity for forty-eight hours, and therefore that it would be possible with safety to clear an island of its infected population one day and restock it with healthy natives a few days later. But it has now been found by experiment that the fly retains its infectivity up to eighty days and it seems probable that once infected a fly harbors the trypanosomes for the rest of its life. It therefore became important to discover how long the flies on the lake shore remained infective after the native population had been removed. Flies were collected at a cleared landing place which was used as a market by the inhabitants of one of the islands, who were highly infected with sleeping-sickness. This constituted a danger to the healthy natives of the mainland who had come to the market from places beyond the area of the disease. The landing was therefore cleared of undergrowth and in a short time the flies disappeared. As the result of many experiments it was concluded that the flies remained infective at least two years after the natives had been removed. This long duration of infectivity can be accounted for only by two theories—long life of the fly or the infection along the lake shore of birds and mammals which become a reservoir of the disease. At present the former theory has not been proved or disproved and of the latter there is no experimental proof.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Dec. 3, 1909.

Discussion in the Chamber of Deputies on Depopulation

Apropos of the discussion of that portion of the budget of the ministry of the interior relating to the protection of young children, M. Gauthier of Clagny called the attention of the Chamber of Deputies to the serious question of depopulation. The alarming figures on this subject for the first semester of the present year were given in The Journal (Nov. 4, 1909, liii, 1833). The Neo-Malthusian League is spreading among women the idea that they have the right to avoid maternity. Since 1887 another league, also intended to promote depopulation, has been working through pamphlets, prospectuses, journals and lectures. There is also a class of criminals who, under the shelter of the league, send to families manuals of debauchery and pornography. In closing M. Gauthier referred to President Roosevelt's epigram that a nation in which the men are unwilling to make war and the women are unwilling to bear children is a nation stricken at the heart. M. Briand, the prime minister, replied that orders had been given that the authors of these shameful works should be severely prosecuted. He believed that the existing laws were sufficient for the purpose, but if not, he should not hesitate to demand more rigorous ones.

Code for the Protection of Young Children

The prefect of police of Paris has just caused a pamphlet to be issued in which are found all the laws, ordinances, and national and municipal instructions which bear on young children. This code for the protection of childhood will be sent to all the municipalities under the jurisdiction of the Paris prefecture, to the medical inspectors, and to the visiting inspectors of children boarded out. In this code will be found all the documents in regard to the obligations imposed on wet-nurses and care-takers, local commissions and medical inspectors of crèches. To this will be added the elementary advice, on the hygiene of infancy, in regard to natural, mixed and artificial feeding, published for mothers and nurses by the Academy of Medicine. The *Oeuvre de protection des enfants du premier âge* gives inestimable service in Paris. Thanks to its incessant efforts, the mortality of children boarded out under its control in the department of the Seine has been only 4.96 per cent. during 1908, while the average of infant mortality during the same year reached the truly frightful figure of 15 per cent. One may moreover form an estimate of the progress made by this organization from the fact that in 1907 the mortality of its nurslings was 5.15 per cent. and in 1900 8.7 per cent.

Repression of the Renting of Children for Begging

It is not rare to see in the streets of Paris beggars who in order to excite the pity of passers-by, carry in their arms during all seasons and at all hours, young children, most frequently lent or rented by irresponsible parents. Believing that this exploitation of infancy affects the health of young children unfavorably, the prefect of the police has just given severe orders for the repression of the criminal practices of those who rent children. After a rapid inquiry to determine the origin of such children, the agents of the police will send the children to an asylum of the public charities (*Assistance Publique*) and moreover the unworthy parents will be prosecuted before the courts.

The Period of Rest for Pregnant and Lying-in Women

A law has just been passed guaranteeing the positions of employed women during pregnancy and lying-in. According to this law, an employer who breaks a contract of employment because of the suspension of work by a woman during the eight consecutive weeks in the period which precedes and follows child-birth is liable for damages to the woman, provided that the latter shall have warned her employer of the reason of her absence.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Nov. 24, 1909.

Personal

Professor v. Franqué, the gynecologist of Giessen, has refused a call to Göttingen as successor to Professor Runge, deceased.——Dr. Treutlein, privatdocent at Würzburg, who has for some years been general director of the public health department of the Republic of Bolivia, has left for political reasons and has returned to Würzburg as instructor in naval, military and tropical hygiene.——Professor Bernstein, director of the physiologic institute at Halle, will celebrate his seventieth birthday, December 8.——Professor Schirmer, head of the eye clinic at Strasburg, has resigned. This is somewhat surprising as Schirmer is only 45.

Motherhood Insurance

The plan for insurance of women about to become mothers, which has been undertaken under private auspices in Baden, has been noticed in a previous letter. The proposal to make this a government undertaking applying to the whole empire has little prospect of success as the necessary annual expense of $70,000,000 (280,000,000 marks) would be more than the government would be justified in expending in the present state of its finances. Besides it is believed that sufficient relief for women and nurslings is afforded by the recent legislation in favor of women workers and by the proposed imperial insurance law.

Alcohol and Crime

An investigation into the relations between alcoholic intoxication and crime has been ordered by the Bavarian department of justice, confined at first to cases of serious offences against the criminal law. The investigation is to begin with Jan. 1, 1910. Those cases are to be included in which the crime was committed under the influence of intoxicants, or which can be traced to the habitual use of alcohol.

Limitation of Foreign Students at Strasburg Medical Clinics

Of late years the number of foreign female auditors (*hospitantinnen*) at the clinics has increased so considerably that the native students feel themselves placed at the disadvantage by the preemption of the best places and have made complaint accordingly. It has been settled that women who are not matriculants shall be allowed in future to visit the clinics as auditors only under condition that they can show evidence of a sufficient previous education. This evidence must be furnished by the presentation of a certificate that the individual is prepared for the regular study of medicine in a university or institution of equal grade in his own country. Exceptions are to be allowed for such auditors as take only special medical lectures, but are not pursuing a regular medical course.

Change of Physican at Lahmann's Sanatorium

At the end of next year Prof. v. Düring, director of the well known Lahmann's sanatorium, "The White Stag," at Dresden, will resign his position. What reasons have induced him to give up so desirable a place are not known; probably some trouble with the proprietors has arisen, as is usual, because the medical interest has conflicted with the commercial interest of the proprietors of the sanatorium. Similar conditions are seen in other institutions, especially in Brehmer's sanatorium at Görbersdorf, which is managed by the heirs of the renowned founder of the physical-dietetic treatment of consumption. Since the death of Brehmer, the medical management of the institution is changed almost annually. That the interests of the patients must suffer with such frequent change of physicians is readily understood. Prof. v. Düring is essentially a dermatologist. In this specialty he was professor for many years at the military school at Constantinople in the service of the Turkish government and won great distinction in this position. For this reason he received the title of pasha from the former sultan. From Constantinople he was called to Kiel a few years ago as professor extraordinary of dermatology. A short time thereafter he gave up his position and after the death of Lahmann he undertook the direction of his sanatorium. His assistants also leave the institution with him.

Typhoid Bacillus Carriers

In a small epidemic of fourteen cases of typhoid fever in Westphalia it was ascertained that the germs of the disease were introduced with the milk that was furnished by a dealer in the place in whose family there was found a bacillus carrier who had probably harbored bacilli in his intestine since an attack of typhoid which he experienced nine years before. In another village of Westphalia a cook who had typhoid twenty years ago has communicated the disease in the course of time to members of the family of almost all the persons in whose service she has been and has been responsible for at least twenty-four such cases.

Pharmacology

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION]

BISMUTH BETA-NAPHTHOLATE

W. A. Puckner and W. S. Hilpert

Uniformity in composition of medicines, official in the U. S. Pharmacopœia, is secured by the method of preparation or the tests of purity and strength for which that book provides. As a rule there are no standards of purity or strength for substances that are not included in the Pharmacopœia, with the result that substances nominally supposed to be identical frequently are found to vary in composition not only with the brand, but often with different batches of the same brand. The Council on Pharmacy and Chemistry aims to establish standards for these articles, so as to insure the uniformity of unofficial remedies and to overcome this stumbling block to therapeutic accuracy and efficiency. It is in connection with this line of work that the examinations of different brands of bismuth beta-naphtholate, about to be described, were made. The results are published for the specific purpose of showing the need of such control of unofficial articles.

One of the incidental results of these examinations is to show that even different specimens of what is supposed to be the same product, may differ widely in composition. It is especially interesting in this particular case, because the firm whose product is shown to have possessed such lack of uniformity is the one that holds patents which are claimed to give it the exclusive right to make this product. It sells the preparation under a protected (trade-marked) name, and curiously enough it maintained that other preparations of bismuth beta-naphtholate which appeared on the market shortly after this protected preparation was introduced were "crude toxic and irritant imitations which are mere mechanical mixtures of bismuth salts and naphthol."

THE DRUG ITSELF

Bismuth beta-naphtholate is practically insoluble in water and is only slightly soluble in dilute acids. It is, therefore, not materially changed in the stomach. The intestinal fluids, however, are said to decompose it into its constituents and according to the literature on the subject when thus acted on the bismuth exerts an astringent action, while the naphthol acts as an antiseptic. The composition of bismuth beta-naptholate has not been definitely determined; the following chemical formulas are variously assigned to it: $C_{10}H_7O(BiO)$ (Schmidt's Pharm. Chemie.); $Bi_2O_2(OH)C_{10}H_7O$ (National Dispensatory; Merck's Index; British *Codex*; Chemische Fabrik von Heyden; Hager's Handbuch der Pharm. Praxis); and $Bi(C_{10}H_7O)_3.3H_2O$ (U. S. Dispensatory).

The composition of bismuth salts varies so that it is probable that a bismuth beta-naphtholate of definite composition can only be made with great difficulty. However, since the therapeutic value of this preparation must depend on the bismuth and on the "combined naphthol" contents, it is important that the substance used by physicians should be of fairly uniform composition. Its therapeutic value is said to depend largely on its freedom from uncombined or free naphthol and the product should, therefore, be relatively free from this constituent. With the object of determining the uniformity of composition of bismuth beta-naphtholate, as it is now available, the various products found on the market were analyzed, to determine their bismuth and free and "combined naphthol" contents.

LABORATORY FINDINGS

Bismuth beta-naphtholate is found on the market in powder and in tablet form. The powder is light-brown or grayish-brown, without odor and practically tasteless, insoluble in water and only partially so in alcohol. Strong acids decompose it into its components which by proper manipulation can be separated and estimated.

Several specimens, both of tablets and powder, of different brands were obtained, some from the manufacturers and others on the open market. In appearance the tablets were practically alike, but the powder form varied from a light grayish color through a pinkish-brown to dark brown. Experiments were made to determine the bismuth and combined naphthol contents by decomposing the bismuth beta-naphtholate and separating the constituents. Since bismuth beta-naphtholate is insoluble in chloroform, substances other than bismuth beta-naphtholate, including free naphthol were estimated by direct extraction of the specimens with chloroform or ether. The results of these estimations[1] are given in the following table:

Brand.	Bismuth.	"Total Naphthol."	Sol. in Chloroform or Ether.
Orphol (Chemische Fabrik von Heyden).			
Specimen 1 (tablets)*	67.12	10.57	3.85
Specimen 2 (tablets)	61.05	21.58	0.40
Specimen 3 (powder)	69.08	21.50	18.46
Specimen 4 (powder)	68.21	24.05	0.40
Bismuth Beta-Naphtholate (H. K. Mulford Co.).			
Specimen 1 (tablets)	56.47	6.89	4.89
Specimen 2 (tablets)	51.27	18.84	3.21
Bismuth Beta-Naphtholate (Powers-Weightman-Rosengarten Co.)			
Specimen 1 (powder)	75.30	15.56	0.19
Specimen 2 (powder)	75.07	15.56	0.33

* The percentages given were calculated on the assumption that the tablets contained the amount of substance claimed.

A noticeable lack of uniformity among the products is disclosed by the table. Thus the bismuth content ranges from 51.27 per cent. in a specimen of one brand to 75.30 per cent. in another brand. This alone certainly shows the necessity of some control and regulation in the manufacture of the products. Among the specimens of a single brand we find the bismuth varying from 61.05 to 69.08 per cent., a condition which should not exist and which by care in preparation can be avoided.

A similar variation exists in the naphthol content which ranged from 6.89 to 21.58 per cent. It was found that the specimens varied not only in the quantity of actual naphthol present but also in the composition of what was supposed to be naphthol. The material which was extracted weighed and recorded as "total" or "combined naphthol" should represent the content of beta-naphthol. Some specimens examined failed to respond to the usual tests for beta-naphthol. The same may be said of the so-called "free naphthol," or more correctly, "ether- and chloroform-soluble matter." As indicated by the solubility in chloroform or in ether the various products were found to contain from 0.19 per cent. to about 18.46 per cent. soluble matter.

It is noteworthy that the products of the same brand, manufactured under the same patent, bearing the same trade-marked name on identical labels—should vary from 61 to 69 per cent. in the bismuth content, from 11 to 24 per cent. in naphthol content, and from 0.40 to 18.0 per cent. in matter soluble in chloroform. If such a condition exists in a product so identified and protected what may not be expected of products for which no claims of uniformity are made or implied, by patents or trademarks? As a means of comparison of the compositions of the different brands examined the following summary is given:

SUMMARY OF FINDINGS

Bismuth Beta-Naphtholate (Powers-Weightman-Rosengarten Co.).—The most important features shown by the analysis of this product are high bismuth content and practical freedom from free naphthol. The two specimens of this brand examined—one purchased on the open market and the other submitted by the company—were found to be almost identical, as is shown by the table. Specimen 1 contained 75.30 per cent. bismuth, 15.56 per cent. naphthol, and 0.19 per cent. free naphthol; specimen 2 contained 75.07 per cent. bismuth, 15.56 per cent. naphthol, and 0.33 per cent. free naphthol. This brand contained the highest percentage of bismuth and the lowest content of free naphthol of any examined.

Orphol (Chemische Fabrik von Heyden).—The specimens of Orphol examined may well be specified as "old" and "new" Orphol. The "old" specimens were obtained and analyzed some time ago, while the "new" specimens were obtained only recently. Among the old specimens, that is those received and examined some time ago, the bismuth content averaged about 68 per cent., the matter recorded as "total naphthol" about 16 per cent., and the chloroform-soluble matter about 11 per cent., the highest content of the latter found in any brand. The so-called naphthol of these old specimens in many cases failed to respond to the usual tests for naphthol, and exhibited none of the physical properties of naphthol, so that it was concluded that the greater part of the naphthol used in the preparation of the product had in some way, by oxidation or nitration probably been converted into decomposition products, and so no longer gave naphthol reactions. In other words, naphthol, as such, was not present in the preparation.

The chloroform-soluble material consisted of not free naphthol but was chiefly a bismuth organic compound, which also gave none of the free naphthol reactions. This constituent was found in quantities as high as 18 per cent., and just to that extent the product was contaminated and made uncertain.

These specimens, considering their composition, could hardly be called bismuth beta-naphtholate in spite of the patent rights and trade-marked name, and they stand out as an example of the kind of product that may be expected while no control in the manufacture is demanded. A specimen of Orphol tablets examined some time ago was found to contain 67.12 per cent. bismuth, 10.57 per cent. "naphthol," and 3.85 per cent. chloroform soluble matter. A specimen examined more recently contained about 61 per cent. bismuth, 21.6 per cent. naphthol, and from 0.3 to 0.4 per cent. chloroform soluble matter. Although the new tablets show a somewhat diminished bismuth content, the naphthol has been materially increased and free naphthol practically eliminated, showing on the whole an improvement over the older tablets.

The most recent specimen of Orphol examined contains 68.21 per cent. bismuth, 24.05 per cent. naphthol, and 0.40 per cent. chloroform soluble matter. A comparison of this analysis with estimations made on specimens some time ago indicates the extent to which the product has been improved. The combined naphthol, which is important for the proper therapeutic action of the product is well above the average and the free naphthol which is a very objectionable ingredient is now almost entirely eliminated, to the benefit of the profession and the credit of the manufacturers.

Bismuth Beta-Naphtholate Tablets. (H. K. Mulford Co.).—A specimen of these tablets was examined some time ago and the bismuth beta-naphtholate was found to contain 56.47 per cent. bismuth, 6.89 per cent. naphthol, and 4.89 per cent. chloroform soluble matter. A more recent product was examined and found to contain 51.27 per cent. bismuth, 18.84 per cent. combined naphthol and 3.21 per cent. chloroform soluble matter. Here again attention is called to the endeavor and partial success in the improvement of the product. Although the new tablets have a slightly lower bismuth content, the total naphthol has been appreciably increased, while a certain amount of the undesirable free naphthol has been eliminated.

---

[1] The analytical details are contained in a paper presented to the scientific section of the American Pharmaceutical Association, 1909, and will appear in the printed proceedings of that body and also in the Annual Report of the Laboratory of the American Medical Association.

A STANDARD NEEDED AND RECOMMENDED

The above summary of the results of analysis for the various products and specimens brings out more distinctly the necessity of a standard for the control of the future manufacture of bismuth beta-naphtholate, insuring a product on which physicians can rely for uniform effects.

To establish a standard for bismuth beta-naphtholate, both the highest possible and the highest available purity must be considered. It would be useless to set a standard which could not be conformed to and yet one must be chosen which will eliminate the poorer and more variable products. For bismuth beta-naphtholate the following standard is recommended:

Bismuth beta-naphtholate should contain not less than 60 per cent. bismuth, 15 per cent. total naphthol, which should respond to tests for beta-naphthol, nor more than 1 per cent. of ether- or chloroform-soluble matter, when analyzed according to the methods of analysis employed in this investigation.

PHARMACOPEIAL REVISION

Report of the Therapeutic Committee of the British Medical Association

The report of the therapeutic committee of the British Medical Association on the revision of the British Pharmacopeia (supplement to the *British Medical Journal*, 1908, ii, 319) is of interest to American physicians because it clearly indicates that on the question of scope or content of the Pharmacopeia, the one question that is of prime importance to the physician, medical men are not only capable of outlining rational general principles but are also able to give, in detail, reasons that will appeal to thinking men, quite regardless of whether the latter have any special knowledge of medicines.

The general principles adopted by the committee on therapeutics to guide them in determining on the proposed additions and deletions are as follows:

> "1. Crude drugs which contain an active ingredient possessing all the desirable actions of the crude drug might be replaced by this active ingredient if it can be obtained commercially and its identification and purity ensured. If such an active principle is official, the crude drug might be deleted. For example, jaborandi leaves, coca leaves, elaterium and many crude drugs yielding only volatile oils might be deleted.
>
> "2. Drugs and their preparations possessing no obvious and serviceable action should be deleted, e. g., arnica rhizome, cuspari bark, hemidesmus root, lupulin, mezereon bark, serpentary rhizome.
>
> "3. Unnecessary duplication of the preparations of a drug should be avoided. Thus one 1 per cent. solution of a morphine salt, or one solid extract of belladonna, is sufficient.
>
> "4. Purely diluent preparations of a drug should, as far as possible, be avoided, e. g., solutions of potassium permanganate, almond mixture.
>
> "5. Substances which do not require to be defined officially for the protection of the practitioner, or the vendor or purchaser, e. g., prunes, figs, brandy, sherry, might be omitted.
>
> "6. Substances of no therapeutic importance, which are used only in the making of preparations and are not contained in the final products, should be deleted or transferred to an appendix, e. g., benzol, solution of iron persulphate."

These principles show very clearly that the therapeutic committee of the British Medical Association has in view a pharmacopeia intended to serve the best interests of members of our profession, an aim that should be self-evident but one which is commonly overlooked in considering what the Pharmacopeia should be.

These principles also indicate that the problems that are confronting British physicians are in no way different from those that we must contend with in the revision of our Pharmacopeia; and they further suggest that if the real purposes of the Pharmacopeia could be kept steadfastly in mind the problems of its revision would be enormously simplified.

While the therapeutic committee of the British Medical Association does not specifically state that the true therapeutic value of a substance should be the sole criterion for admission, the principles as stated show the trend of opinion. In curious contrast to this evidenced thought is the sentiment, altogether too freely adopted in our own country, that the extent of use of a substance be considered as the sole justification for admission to or retention in the Pharmacopeia. Unfortunately the degree of popularity which a preparation enjoys frequently stands in no relation to its real value or even to its reputation among the leading clinical authorities, at least so far as this country is concerned.

The *British Medical Journal*, commenting editorially on the report of the therapeutic committee, points out that, while several recommendations for the omission of drugs from the future editions of the British Pharmacopeia may seem somewhat drastic, they are nevertheless fully justified by the general principles adopted as a guide for the committee.

Altogether the suggested deletions number about one hundred and include many articles and preparations which in former times were very familiar, but which in the light of more accurate knowledge and greater experience are known to be unnecessary or valueless. Other articles like prunes, figs and brandy are recommended for omission because they are not usually prescribed as such and require no official descriptions, being commercial products that vary in quality and price. Altogether it is quite apparent that the therapeutic committee has given much thought to the work. The report should be read by all who are directly interested in the question of pharmacopeial revision.

A perusal of the list of articles recommended for admission is to the advantage of our own Pharmacopeia, since most of these articles are now official in the U. S. Pharmacopeia. The proposed admissions include: extract of malt, ethyl chlorid, methyl salicylate, guaiacol, solution of formaldehyd, chloralamid, hexamethylenamin, solution of cresol and soap, and antidiphtheric serum; also the following unofficial articles: aspirin, or acetyl salicylic acid, a suprarenal preparation, veronal, a soluble preparation of theobromin, orthoform, a less toxic substitute for cocain, and some articles of minor importance.

We in this country have made at least a good beginning in connection with the coming revision of our Pharmacopeia, as is shown by the reports of the several section committees (The Journal A. M. A., Sept. 4, 1909, p. 791). In an editorial (Oct. 30, 1909, p. 1491) we stated that the methods pursued concerning admissions by the last committee on revision were not such as to appeal to the medical profession, too little pains having been taken to determine how well founded were the wishes represented as favoring admissions. It will be well, therefore, to see that in the forthcoming revision of the Pharmacopeia such methods are followed as will secure a representation of the practices of progressive medical men.

With the report of the therapeutic committee of the British Medical Association as an illustration of the practical possibilities, with the reports of the section committees of the American Medical Association as a demonstration of the feasibility of doing even more efficient work, and with the admirable scheme for revision suggested by Torald Sollmann (The Journal, Nov. 6, 1909, p. 1543) as a practicable solution of pharmacopeial revision problems to look forward to, it would appear as though the way for securing a better and more representative book for the medical practitioner was clearly outlined. It remains for members of the medical profession to say whether they will have a Pharmacopeia representing the foremost thought in therapeutics, or one which is practically valueless for this purpose.

As medical men we must not lose sight of the fact that the shortcomings of the Pharmacopeia, so far as scope and content are concerned, are in reality a measure of our own neglect of a plain duty, and that unless all classes of medical practitioners are willing to take an active interest in the matter of pharmacopeial revision it will be difficult indeed to avoid the odium that must attach itself to us should the forthcoming ninth edition of the U. S. Pharmacopeia fail to reflect adequately the best, and only the best pharmacal therapy in American medicine.

COLLARGOL

Report of the Council on Pharmacy and Chemistry

The following recommendation was submitted to the Council:

A letter from Dr. S. Solis Cohen to the Editor of THE JOURNAL has been transmitted to the Council. In this letter Dr. Cohen states that his communication to the chairman of the collargol commission should have been published with the Council's rejoinder to Schering & Glatz's reply, which appeared in THE JOURNAL, July 10, 1909. In view of Dr. Cohen's request, it is recommended that publication of his letter of dissent to the majority's findings be authorized.

The recommendation having been adopted, the letter of Dr. S. Solis Cohen is here published.

W. A. PUCKNER, Secretary.

PHILADELPHIA, May 3, 1909.

DR. W. A. PUCKNER, Chicago, Ill.

My Dear Dr. Puckner:—I have received your letter of April 30, enclosing copy of Schering & Glatz's report and of Dr. Edsall's explanatory note.

I still feel that the committee made a mistake in not permitting Messrs. Schering & Glatz to be heard before deciding on a report, although this error was in a measure corrected by submitting to them the proposed report and receiving their written comment on it before publication.

The explanatory note involves reaffirmation of a number of points of fact, theory and attitude concerning which I differed with the majority of the committee, and I am therefore unable to give it my unreserved approval. As an instance of what I believe to be hypercriticism on the part of the committee, I would cite that portion of the explanatory note relating to the Hocheisen quotation. The fact remains that Hocheisen used the word "wertvolles," and Schering & Glatz admit that they should have translated it "valuable" instead of "invaluable." The committee shows that what Hocheisen really said was: "Hence collargol is no specific, but is an aid in suitable cases," and that further on, after having described types of unsuitable cases, he adds: "Used according to these principles, collargol injections constitute a valuable measure in cases of puerperal sepsis." Messrs. Schering & Glatz now condense this into: "Collargol is a valuable aid in cases of puerperal sepsis."

It seems to me that both Messrs. Schering & Glatz and the committee are in part at fault. That is to say, Messrs. Schering & Glatz should quote exactly what an author says, with his limitations and in his exact language. They are not justified in leaving out the limiting phrase, "Used according to these principles;" they are not justified in leaving out the limiting phrase, "no specific." On the other hand, it must be admitted that the opinion of the author in this particular instance has been substantially represented in the revised phrase, and that to magnify the importance of the incident is to leave the judicial attitude and approach that of the prosecutor.

My own opinion remains as before, that Messrs. Schering & Glatz claim too much, and that the majority of the committee doubts too much; that collargol is worthy of admittance to the list of recognized nonofficial remedies, and that Messrs. Schering & Glatz should be required to revise their advertising matter in such a way as to give the exact words of every author cited; and that all the limitations and qualifications which an author throws around his opinion should be quoted. On the other hand, they are perfectly justified in quoting experiments and conclusions, clinical observations and recommendations, of investigators and of clinicians who may have formed a favorable opinion concerning the drug or who may have established to their own satisfaction any chemical, clinical or pharmacologic fact concerning it. The evidence being submitted, the reader can draw his own conclusions as to its trustworthiness and authority. It would be manifestly unfair to set up for advertising matter a standard which is not required of text-books, namely, infallibility in observation and logic.

To avoid misunderstanding, however, I would, in conclusion, emphasize again my agreement with the majority of the committee that quotations must be exact, *verbatim et literatim*, and that statements of the results of experimental observations must be made in such a way as to convey the exact facts, and not in so partial a manner that, however innocently, they may mislead readers not familiar with the details of laboratory work.

It is time to stop bandying words in this matter, and come to an agreement and conclusion honorable to all concerned and worthy of the issue. SOLOMON SOLIS COHEN.

Correspondence

Transmission of Bovine Tuberculosis to Human Beings

To the Editor:—It behooves one who writes history to be very sure of his facts. When one attempts to correct history already written, the necessity for accuracy is still more important. These thoughts have been forced on me through the reading of the article by Dr. H. L. K. Shaw in THE JOURNAL for Nov. 27, 1909, on the "Transmission of Bovine Tuberculosis to Children." It has seldom been my misfortune to read a so-called scientific paper with such glaring inaccuracies of statement. Dr. Shaw is evidently very anxious to support Koch in his errors through thick and thin, and evinces an ardor which would be better served by greater accuracy.

To begin with, the conclusions he attributes to Koch at the British Congress for Tuberculosis in 1901 are those given by him in 1908 in Washington, after Koch's errors had been shown up by the work of numerous scientists in various parts of the world. Dr. Shaw complains that Koch has been persistently misquoted, but he seems to have fallen into the bad habit himself. What Koch really said in London in 1901 is as follows:

1. "Human tuberculosis differs from bovine and cannot be transmitted to cattle."

2. "Though the important question whether man is susceptible to bovine tuberculosis at all is not yet absolutely decided, and will not admit of absolute decision to-day or to-morrow, one is, nevertheless, already at liberty to say that if such a susceptibility really exists the infection of human beings is but a very rare occurrence. I should estimate the extent of infection by the milk and flesh of tuberculous cattle, and the butter made of this milk, is hardly greater than that of hereditary transmission, and, therefore, do not deem it advisable to take any measures against it."

No one can read these conclusions without believing that Koch intended to make the practical statement that there was no danger to mankind from tuberculosis of cattle, and very properly this impression has become wide-spread with the laity and the profession.

Koch's conclusions in 1908 are as follows:

1. "The tubercle bacilli of bovine tuberculosis are different from those of human tuberculosis."

2. "Human beings may be infected by bovine tubercle bacilli, but serious diseases from this cause occur very rarely."

3. "Preventive measures against tuberculosis should therefore be directed primarily against the propagation of human tubercle bacilli."

As Dr. Shaw seems to be ignorant of what Koch said in 1901, it is not to be expected that he would appreciate the difference betwen Koch's attitude at that time and at present. In 1901 Koch questioned the possibility of transmission of bovine tuberculosis to man in any form; in 1908 he limited his contention to pulmonary consumption (THE JOURNAL A. M. A., Conference in Camera on Human and Bovine Tuberculosis, Oct. 10, 1908, p. 1262). The stand now taken is entirely different from the former, and Koch has skilfully raised an academic discussion which has befogged the main question, and diverted the attention of some persons from his former blunder.

At the so-called "*conference in camera*," to which Dr. Shaw refers, there were not many present who could report cases of pulmonary tuberculosis due to the bovine bacillus. It must be remembered, however, that this point had never before been raised, and the great majority of those who had studied the question were interested solely in refuting Koch's statement regarding the problematical danger to mankind from tuberculosis of cattle. It is easy to say offhand, as Dr. Shaw does, that "the possibility of contamination had not been fully guarded against" by the English Royal Commission and by Professor Arloing, but this does not prove it. Koch's contention in this case was mere quibbling. It must be remembered also that the German commission in its first report gives one instance of miliary tuberculosis in which the bovine bacillus was found in the lung. Koch declined to accept this case as one of pulmonary tuberculosis due to bovine bacillus, and Dr. Theobald Smith in his attempts to support Koch, found it necessary to explain that these were not cases of pulmonary consumption, because the patient died before open lesions could form. The difference between ordinary pulmonary consumption and miliary tuberculosis is of course known to every medical student, but certainly this case reported by the German commission should be ranked among those of pulmonary tuberculosis due to the bovine bacillus.

Dr. Shaw also makes the statement that, in 1905, I asserted "that the majority of cases of tuberculosis of children were of alimentary origin and due to the bovine bacillus." Again Dr. Shaw is guilty of misquotation. I have never in public or private, in writing or by spoken word made such a statement, nor have I believed it. It may be cruel to ask that Dr. Shaw will read carefully what I have written on this subject, but I certainly have the right to ask this when he professes to quote me.

Dr. Shaw refers to the case of an infant in which, he says, a long chain of circumstantial evidence convicted a cow of being the origin of the disease. When the cow was slaughtered, however, no tuberculosis could be found. It is not strange that the cow did not transmit tuberculosis to this child since it was free of the disease itself. It is hard to understand just what Dr. Shaw wishes to show by this case. Only two conclusions are justified. First, the test may have been at fault; but, second, and more important still, it points to the unreliability of clinical evidence in determining this question.

Dr. Shaw speaks further of a circular letter sent out to members of the American Pediatric Society and leading pathologists. I wish to protest here against any such method of deciding this question. Without wishing to belittle the ability of any of these men, I hold that the question is one that can be determined only by accurate laboratory investigation. Only pathologists and bacteriologists who have made a careful study of this question are competent to express an opinion on it. I grant to every one, of course, the right to read and draw conclusions as to the weight of evidence on one side or the other. Laboratory investigations have shown beyond question that bovine tuberculosis is transmissible to human beings, and that the lesions produced do not differ in any way from those caused by the human bacillus.

Dr. Shaw speaks of the sensational articles "magnifying the great danger of bovine tuberculosis," and quotes Dr. Bensel as deprecating "the spread of alarm in the minds of the public in regard to the danger of tuberculosis from milk." If Dr. Bensel has made any investigations which render him competent to express such an opinion, they have escaped my observation. It may be injurious to have the public believe that milk is the chief cause of tuberculosis in human beings, but when the work of Dr. Park in the city of New York shows that 200, and possibly 300 children die from bovine tuberculosis every year in that city, it seems high time that the profession and public in general should recognize bovine tuberculosis as a serious menace to human health.

Dr. Shaw, while trying to belittle the results of the English Royal Commission, failed to quote the work of the German Imperial Commission, which in fairness he should have given. This commission in 84 cases of tuberculosis in children found that 21, or exactly 25 per cent., showed the bovine type of bacillus, figures which correspond very closely to those given by the English commission.

I would not be understood as belittling the importance of all measures of prevention. I admit freely, as I always have, that as far as our present evidence goes, man is the greatest source of danger to man. I have not, as Dr. Shaw intimates, changed my position on this one particle. Those who are actively engaged in supporting Koch in his blunders, and trying to belittle the importance of bovine tuberculosis as a menace to human health, are, it seems to me, criminally responsible.

I have felt the necessity of speaking plainly in writing this letter, because in the recent and most important suit against the city of Milwaukee brought to prevent the enforcement of its ordinance in regard to bovine tuberculosis, Dr. Shaw's testimony has been made much of by the plaintiffs. I think I have shown that he has misquoted liberally, and if his conclusions have been drawn from such careless reading, they must of course be of no value.

MAZYCK P. RAVENEL, Madison, Wis.

The preceding letter was submitted to Dr. Shaw, who replies as follows:

To the Editor:—Permit me to thank you for this opportunity of replying to Dr. Ravenel's rather bitter attack on my scientific integrity. The main criticism is that I have been inaccurate in the presentation of my quotations. Although I made use of over thirty references Dr. Ravenel challenges but two. The first is that I endeavored to mislead my readers in the matter of Koch's conclusions before the British Congress of Tuberculosis in 1901. My authority and quotation are taken from Professor Koch's address before a joint meeting of Sections I and VII of the International Congress on Tuberculosis last fall and published in full in THE JOURNAL, Oct. 10, 1908, p. 1256. At the beginning of the address Koch states: "The results of these experiments have led me to the conclusions which I first communicated to the British Congress of Tuberculosis in 1901. They are, in substance, as follows: 1. The tubercle bacilli of bovine tuberculosis are different from those of human tuberculosis. 2. Human beings may be infected by bovine tubercle bacilli but serious diseases from this cause occur very rarely. 3. Preventive measures against tuberculosis should therefore be directed primarily against the propagation of human tubercle bacilli." While these conclusions appear in the 1908 address, yet Koch himself distinctly says they were his 1901 conclusions and that he had not changed from them in 1908.

The second accusation of misquotation is in regard to a statement attributed to Dr. Ravenel himself. If Dr. Ravenel has been misquoted and misrepresented, I offer my sincere apology. My quotation was made honestly and taken in good faith from the sworn and personally corrected testimony of Professor Adami of Montreal in certiorari proceedings in a suit between the Board of Health of Montclair, N. J., and the Borden Condensed Milk Co. This testimony is a matter of public record and accessible to Dr. Ravenel.

As I have been accused of careless and dishonest reading, I would like to call attention to just one statement in Dr. Ravenel's letter. He quotes me as saying that "it is easy to say the possibility of contamination had not been fully guarded against by the English Royal Commission and by Professor Arloing." If the reader will refer to my article on page 1807 he will find no such statement regarding the English Commission. The criticism in regard to Professor Arloing's case was not made "offhand" by me, but by Koch and Theobald Smith. (See THE JOURNAL, Oct. 10, 1908, p. 1263.)

The value of everything in this world lies in its true perspective. We must look at the facts in a calm, judicial and temperate manner. It is unfortunate that any bitterness or partisanship should be shown in seeking for the exact truth in a subject so vital to mankind. I, as a medical practitioner, have had my attention called almost exclusively to the medical side of the question; while Dr. Ravenel, in his laboratory work, has probably given almost his entire attention to bovine infection. It is the old story of the shield. I see the gold side while Dr. Ravenel has seen only the silver side. Human infection causes 98.5 per cent. of fatal tuberculosis and bovine tuberculosis causes 1.5 per cent. I have never denied that tuberculous cattle are a menace to public health. I do maintain and insist, however, that we must not in any way minimize the very great and real danger of human contagion and magnify too much the relatively unimportant danger of infection from bovine tuberculosis.

The possible motive of Dr. Ravenel lies both in the concluding paragraph of his letter and in the final paragraph of an address delivered before the American Association of Medical Milk Commissions in Chicago in 1908, which I quote, as follows: "Our statements must be definite and strong. We have the most abundant scientific evidence on which to take our stand, and there will always be those who from one motive or another try to belittle the importance of this question. Such people should not be handled too gently."

HENRY L. K. SHAW, Albany, N. Y.

Miscellany

Impressions of America.—N. Guleke, privat-docent of surgery at Strasburg, was given a traveling scholarship last spring and spent nearly three months in the United States studying the work and equipment of various surgeons, part of his report appearing in the *Münchener med. Wochenschrift* during November. He concludes with the statement that the old saying of the Americans: "We have the big buildings, but over in Germany you have the big men," has ceased to be true. America is producing such big men that the stream of disciples no longer sets exclusively toward Europe; there is a counter-stream which is bound to increase year by year, and the more active the interchange the more rapid the progress all around. He expresses amazement at the luxury of some of the hospitals, but missed in some of them the special room for changing the dressings, which is regarded as indispensable in German hospitals. The American trained nurse is lauded. The almost constant good results with ether in the hands of the Americans explains, he says, why new methods of anesthesia do not take in this country as in Europe. Guleke also expresses surprise at the slowness with which the American surgeons operate, their aim evidently being to refrain from everything that might injure or lower the vitality of any of the tissues in the slightest degree beyond what is absolutely necessary—especially their minutely painstaking measures for hemostasis. He was impressed also with the smallness of the incisions and the lack of retractors used during operations. He comments on the prompt decision for operation which permits surgical interference during the early stages of gastric ulcer or gall-stone disease when in Europe the case would still be for some time longer in the hands of the internists. He also remarks on the comparative disregard of the present status, attention being directed mainly to the anamnesis. In his description of the various operations he witnessed by Crile, Cushing, Meyer, Robinson, Ochsner, Elsberg, the Mayos, and others, he repeatedly emphasizes the perfection of the technic and asepsis. He says of the Atlantic City meeting of the A. M. A., which he attended, that it sems to correspond in every respect to the German *Naturforscher* congresses. The zeal with which the members sat through the entire sessions without signs of fatigue also impressed him; it was so contrary to the custom in the German surgical congresses where members get up and leave during an address. The courtesy in the discussions, etc., also impressed him, and the hearty applause for especially noted members.

A Note on the Faradic Stimulation of the Postcentral Gyrus in Conscious Patients.—The recent work of Sherrington and Grünbaum in accurately delineating the confines of the so-called motor area in the ape by a method of unipolar faradization have greatly revised our idea of cortical localization and led to a confirmation of the results for man by similar stimulation of the cerebral cortex in anesthetized patients. A further unique step, however, has been taken by Harvey Cushing (*Brain*, 1909, xxxii, 44) when he stimulated the postcentral gyrus of the cerebral cortex of two patients in a conscious state, during a "second-stage" operation. The two patients were "afflicted with epileptic attacks inaugurated in each instance by a sensory aura in the right hand." Primary anesthesia and 1/8 gr. of morphin were administered only for the scalp incision and to remove the bone flap. In each case "the patient composedly and promptly recovered from the temporary narcotic effect of the drug," and no pain was experienced during the remainder of the operation. The patients eagerly assisted in the experiments of cortical localization and responded, telling the sensation felt on stimulation of the cerebral cortex. The purpose of the paper is "to record solely the physiologic aspects of these observations, although their surgical aspects are possibly of even greater importance; for if it will be possible in the future to pick out with an electrode areas of the brain from which the sensory aura of a focal convulsion has originated, we shall have advanced a long way toward the possible operative localization of subcortical irritative lesions of the immediate postcentral field. . . . In both of the patients the situation of the central fissure was determined by obtaining characteristic motor responses from the precentral gyrus, these motor responses being attended by no sensation other than that of the forced change of position which accompanies similar movements elicited by stimulation of a peripheral nerve. On the other hand, in both of these patients stimulation of the postcentral convolution gave definite sensory impressions which were likened in one case to a sensation of numbness, and in the other to definite tactual impulses. In both of the patients, furthermore, stimulation of the outlying convolutions gave no response whatever, either of a subjective sensation or of active movement."

The Occurrence of Remissions and Recovery in Tuberculous Meningitis.—There exists among the majority of the medical profession the greatest skepticism with regard to the diagnosis of cases of tuberculous meningitis in which there were remissions of symptoms or in which recovery occurred. Alfred E. Martin (*Brain*, 1909, part 126, xxxii, 209) made a careful analysis of the reports of the London and Vienna hospitals, which show that in 2,166 cases diagnosed as tuberculous meningitis, only 22 patients, or about 1 per cent., were discharged from the hospital cured or relieved, though these figures, Martin says, are perhaps a little too high. A critical review of the literature is also given, and many of the reported cases of remission and of recovery are considered doubtful. Some space is devoted to differential diagnosis and to "methods of confirming the diagnosis," in which are emphasized, that it is impossible to accept a diagnosis of tuberculous meningitis as certain if it is based solely on the clinical symptoms, though the possibility may be very great; and the importance of the complete lumbar puncture method of diagnosis. One of Martin's conclusions is that "undoubtedly long remissions and even recoveries do occur in tuberculous meningitis. Recoveries are possibly more frequent than has been believed, since no fewer than twenty undoubted cases have been recorded since 1894, while other cases of recovery have been published in which the same definite proof of the nature of the disease has not been afforded, but some of which probably were true cases of tuberculous meningitis. In these cases either the resistance of the individual is so much greater than usual that the disease is checked early in its course, or the virulence of the bacilli is so much less than usual that the lesions in the meninges become localized and later undergo a fibrous change. The lesions in the meninges may at a later period form the focus of a fresh infection, which usually terminates fatally, and consequently the prognosis in these cases must be guarded. No treatment up to the present has been discovered which has any specific effect in promoting the favorable termination of the disease."

Poisoning from Illuminating Gas.—A. Robin's advice is to keep the patient seated instead of reclining, thus reducing the congestion in the head, sprinkle with cold water, and rub the legs vigorously while keeping up artificial respiration; possibly traction of the tongue (*Laborde*) will be sufficient. Venesection should be done as promptly as possible, withdrawing about 500 gm., nearly 15 ounces, of blood. As soon as this has been done, apply cupping to the base of the lungs, front and rear, at the side and at the back of the neck. The patient should then be made to inhale oxygen; "he can never be given enough, nor can it be kept up long enough." A purgative enema should then be given, possibly 15 gm. each of sodium sulphate and senna in 500 gm. water. In one case in which all these measures failed, he finally succeeded by intravenous infusion of 500 gm. of physiologic salt solution. The neuralgias which are liable to develop later should not be treated with the usual drugs as the latter have a more or less toxic action on the red corpuscles; morphin should be the main reliance. Any paralysis developing should be combated with electricity and massage, anemia with sulphur baths and iron. His article is summarized in the *Gazette Méd. Belge*, 1909, xxii, 79.

The Influence of Hot Baths on Pulse Frequency, Blood-Pressure, Body Temperature, Breathing Volume and Alveolar Tension in Man.—The physiologic effects of hot and cold baths on the normal, healthy human individual were demonstrated by Leonard Hill and Martin Flack (*Jour. Physiol.*, 1909, xxxviii, 441). The tabulated results afford a ready reference of the principal physiologic effects of hot and cold baths.

Such results should be taken into account in the consideration of the indication or contraindication of hot or cold baths in clinical cases. It is shown "that immersion up to the neck in a hot bath (110-105 F.) raises the mouth, axilla and rectal temperature up to 102.5-104.6 F. in fifteen or thirty minutes. This rise of temperature is accompanied by greatly increased pulse frequency (up to 160), and lowered blood-pressure (down to 60), and loss of the mechanism which compensates for the influence of gravity on the circulation. The rise of body temperature is also accompanied in every case but one by greatly increased breathing frequency and volume (even up to 50 liters), accompanied by a notable fall of carbon dioxid tension (down to 3.07), and corresponding rise in oxygen tension of the alveolar air. Owing to the washing-out effect of and increased oxygenation produced by this heat dyspnea, a student is able to hold his breath after a hot bath two and a half times as long as normally. A cold shower constricts the skin and lowers the axillary and mouth temperatures to normal or subnormal, but not the rectal temperature; it lowers the pulse frequency, increases its fulness, raises the blood-pressure and stops the faintness. The breathing volume and alveolar tensions return to normal after the shower."

A Constant Bursa in Relation with the Bundle of His.—E. J. Curran (*Anatomischer Anzeiger*, Sept. 1, 1909, xxxv, 89) from a study of human, calves' and sheeps' hearts points out the following new facts and considerations concerning the auriculoventricular bundle of His. There is a bursa of lubricating mechanism in constant relation with the auriculoventricular bundle, in view of which the possibility of bursitis must be considered in connection with certain cardiac symptoms, and with conditions met with in acute febrile diseases, such as acute rheumatism, endocarditis, etc. The bursa is capable of facilitating the extension of any endocardial process along the course of the conducting system, on account of its anatomical relationship with the endocardium, and of the fact that even small twigs of the auriculoventricular bundle which lie immediately under the endocardium are surrounded with cellular tissue, the spaces of which are continuous with the main bursa. The existence of the bursa tends to prove either that the auriculoventricular bundle does not contract at all, or that it contracts in a different way and at a different time from the contraction of the ventricle. The striking gross resemblance of the reticulum in the calves' and sheep's hearts to a nerve ganglion, and its connection with all parts of both auricles through three large trunks and a number of small twigs and not, as was once thought, merely arising in the right auricle only, is very evident when it is carefully dissected out. These connections point to the possibility of the contraction wave either beginning in the reticulum and proceeding through its branches to all parts of both auricles, or to its coming from all parts of both auricles to meet at the reticulum. In this case there would be a probability of each auricle controlling the time of contraction of the corresponding ventricle, and the meeting at the reticulum of the various bundles of fibers from both auricles and proceeding thence to the ventricles as the auriculoventricular bundle, would merely mean an economy of space.

The Relationship Between the Thyroid and Parathyroids.—J. Halpenny and F. D. Thompson (*Anat. Anz.*, 1909, xxxiv, 376) made a study of the parathyroids of the dog after extirpation of the thyroids, and found that to all intents and purposes the parathyroids become converted into thyroid tissue after such an operation. "The most noticeable feature about the thyroid tissue which has developed from parathyroid is the irregular shape of the vesicles, but the appearance thus presented is strikingly similar to that which is found in the thyroid gland after parathyroidectomy." Aside from the vesicles, there is found tissue in the normal thyroid which seems identical with that of the parathyroids, and "there seems to be no escape from the conclusion that in mammals the thyroid and parathyroid tissues are related to each other, and that the connections are not only physiologic, but anatomic." There being no symptoms after removal of the thyroids, when the parathyroids are left behind, a second operation, in which the parathyroids were removed, was performed. "After removal of the altered parathyroids, the animal showed practically no symptoms for a month, but after this period it developed tremors, became restless and idiotic, and suffered from conjunctivitis, loss of hair and eczema. Death occurred forty-four days after the second operation, and there was no typical tetany at any time."

Classification of Sputum Findings.—I. G. Gabrilowitsch proposes as an improvement on the present methods of classification the following four groups as sufficiently accurate to class the ordinary run of cases: 1. From 1 to 10 bacilli in entire preparation. 2. From 1 to 10 bacilli in each field. 3. More than 10 bacilli in each field. 4. Multitudes of bacilli in each field. In his communication in the *Russki Vrach*, 1909, viii, 298, he shows how the outcome in large numbers of cases corresponded to the above grouping, and that more minute classification is superfluous.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

STOVAIN—NOT A NEW ANESTHETIC

To the Editor:—Please refer me to the literature on the new anesthetic, stovain. F. T. Bascom, Rochester, N. Y.

Answer.—Stovain is not in any proper sense a new anesthetic; it was discovered by Fourneau and the discovery was presented in his name to the Academy of Sciences by Haller in February, 1904. It has a considerable literature. References to the modification of spinal anesthesia suggested by T. Jonnesco are given in The Journal, Nov. 27, 1909, p. 1831. Newspaper accounts have generally misrepresented the character of Jonnesco's modification and have designated him as the discoverer of stovain and frequently have omitted reference to his use of strychnin as an adjuvant. A full description of stovain can be found in New and Nonofficial Remedies, p. 123.

Below are given references to some of the articles on the use of stovain which have appeared in English or which have been abstracted in The Journal. An exhaustive list of the literature on the subject would require too much space.

Coakley, C. G.: Report on the Use of Stovain, *Med. News*, New York, April 15, 1905.

Schiff: Stovain as a Local Anesthetic, *Deutsch. med. Wchnschr.*, Aug. 31, 1905; abstr. in The Journal A. M. A., Oct. 14, 1905, p. 1209.

Trautenroth: Intoxication from Stovain, *Deutsch. med. Wchnschr.*, 1906, xxxii, No. 7; abstr. in The Journal A. M. A., April 14, 1906, p. 1147.

Munchmeyer, O.: Spinal Stovain Anesthesia, *Beitr. z. klin. Chir.*, August, 1908, lix; abstr. in The Journal A. M. A., Oct. 10, 1908, p. 1287.

Willis, C. S., and Wallace, D.: Ten Cases of Spinal Anesthesia, *Australasian Med. Gaz.*, Nov. 20, 1907.

HEROIN HYDROCHLORID AND OPIUM

To the Editor:—Please state the relative value of heroin hydrochlorid and opium. How much opium does one grain of heroin represent?

H. G. HEANEY, Corpus Christi, Tex.

ANSWER.—Heroin hydrochlorid is described in New and Nonofficial Remedies, pp. 95-97. It will be noted that this description shows that heroin is not a native constituent of opium, but is a synthetic derivative of morphin. We cannot state therefore just how much opium one grain represents but can give only the relative dosage, the dose of heroin being from 0.0025 to 0.005 gm. (1/24 to 1/12 grain), while the average dose of opium is 0.06 gm. (1 grain).

The Public Service

Medical Department of the Army

Changes for the week ended Dec. 11, 1909:

Eastman, William R., capt., granted leave of absence for 2 months, when relieved from duty in the Philippines Division.

Baker, Frank C., major, granted leave of absence for 20 days.

Ruffner, Ernest L., Hallovan, Paul S., Phalen, James H., Billingslea, Charles C., capts., med. corps; and Sievers, Robert E., Koyle, Fred T., Myers, William H., 1st lieuts., M .R. C., relieved from duty in Philippines Division, March 15, 1910, and directed on arrival at San Francisco, to report to the Adjutant General of the Army for further orders.

Pipes, Henry F., capt., ordered to New York and Chicago, to study the manufacture and manipulation of the *x*-ray machine.

Cofer, L. E., asst.-surgeon-general, directed to proceed to Ellis Island and Staten Island, N. Y., on special temporary duty.

Irwin, Fairfax, surgeon, leave granted for 1 month from Nov. 22, 1909, amended to read from November 26.

Carter, H. R., surgeon, granted 10 days' leave of absence from Nov. 25, 1909, on account of sickness.

Wasdin, Eugene, surgeon, granted 1 month's leave of absence from Nov. 22, 1909, on account of sickness.

White, J. H., surgeon, granted 10 days' leave of absence from Dec. 1, 1909.

McMullen, John, P. A. surgeon, granted 7 days' leave of absence from Nov. 23, 1909, under paragraph 191, Service Regulations.

von Ezdorf, R. H., and Amesse, J. W [illegible] .led to represent the Service at the Fourth [illegible] Convention of American Republics, to be h [illegible] Rica, Dec. 25, 1909, to January 2, 1910.

Foster, M. H., P. A. surgeon, leave of absence granted for 15 days, en route, amended to read 6 days from November 12, 1909.

Billings, W. C., and Gwyn, M. K., P. A. surgeons, detailed as members of a Revenue-Cutter Service Retiring Board to meet at Arundel Cove, Md., Dec. 9, 1909.

Robinson, D. E., P. A. surgeon, granted 28 days' leave of absence from Nov. 9, 1909, on account of sickness.

McClintic, T. B., P. A. surgeon, granted 6 days' leave of absence from Nov. 19, 1909, under paragraph 191, Service Regulations.

Schereschewsky, J. W., P. A. surgeon, directed to report at Bureau on special temporary duty.

Ebersole, R. E., P. A. surgeon, leave of absence granted for 2 months from Aug. 12, 1909, amended to read 1 month and 29 days from Aug. 25, 1909.

Robertson, H. McG., P. A surgeon, granted 4 days' leave of absence from December 4, 1909.

Sweet, Ernest A., P. A. surgeon, granted 10 days' leave of absence from Nov. 25, 1909.

Marshall, E. R., asst.-surgeon, granted 1 month's leave of absence from Dec. 10, 1909.

Bailey, C. A., acting asst.-surgeon, granted 20 days' leave of absence from Dec. 12, 1909.

Deerhake, Wm. A., acting asst.-surgeon, granted 2 days' leave of absence in November, 1909, under paragraph 210, Service Regulations.

Schwartz, Louis, acting asst.-surgeon, granted 2 days' leave of absence, Nov. 24 and 30, 1909, without pay.

Wakefield, H. C., acting asst.-surgeon, granted 7 days' leave of absence from Nov. 22, 1909, under paragraph 210, Service Regulations.

BOARD CONVENED

Board of medical officers convened to meet at San Francisco, Cal., Dec. 1, 1909, for the purpose of examining an alien. Detail for the board: Passed Assistant Surgeon W. W. King, chairman; Passed Assistant Surgeon F. E. Trotter; Assistant Surgeon R. A. C. Wollenberg, recorder.

Health Reports

The following have been reported to the Public Health Service, during the week ended Dec. 3, 1909:

SMALLPOX—UNITED STATES

Alabama: Montgomery, Nov. 13-20, 12 cases; Birmingham, 1 case.
District of Columbia: Washington, Nov. 13-20, 1 case.
Florida: Jacksonville, Nov. 13-20, 1 case.
Georgia: Macon, Nov. 15-28, 5 cases.
Indiana: Muncie, Nov. 13-20, 2 cases.
Kansas: Kansas City, Nov. 13-20, 3 cases.
North Dakota: Grand Forks County, Sept. 1-30, 2 cases.
Utah, Oct. 1-31, 117 cases, 1 death, in 8 counties.
Washington: Spokane, Nov. 6-13, 1 case.
Wisconsin: La Crosse, Nov. 13-20, 1 case.

SMALLPOX—INSULAR

Philippine Islands: Manila, Oct. 9-23, 2 cases.

SMALLPOX—FOREIGN

Brazil: Bahia, Oct. 15-22, 15 cases, 10 deaths; Para, Oct. 23-30, 1 case, 1 death; Pernambuco, Sept. 1-15, 20 deaths.
China: Amoy, Oct. 9-16, 1 death.
Egypt: Suez, Oct. 14-Nov. 4, 1 case, 2 deaths.
India: Madras, Oct. 9-15, 1 death.
Italy, general, Nov. 1-14, 82 deaths; Naples, Nov. 7-14, 20 cases, 7 deaths.
Mexico: Mexico City, Oct. 2-9, 4 deaths; Oct. 16-23, 2 deaths; Monterey, Oct. 14-21, 1 death.
Persia: Guilan, province, Oct. 4, present; Mazanderan, present.
Russia: Libau, Nov. 1-7, 2 cases, 1 death; Riga, Aug. 1-31, 18 cases, 12 deaths; Sept. 1-30, 11 cases, 3 deaths.
Spain: Almeria, Oct. 1-31, 3 deaths; Madrid, 103 deaths.

YELLOW FEVER

Brazil: Bahia, Oct. 15-22, 1 case, 1 death; Manaos, Oct. 16-23, 1 death; Para, Oct. 23-Nov. 6, 8 cases, 7 deaths.
Ecuador: Guayaquil, Oct. 9-23, 6 deaths; Venezuela: La Guaira, Oct. 27-Nov. 6, 5 cases, 2 deaths, in vicinity.

CHOLERA—INSULAR

Philippine Islands: Manila, Oct. 9-16, 15 cases, 12 deaths; Oct. 16-23, 18 cases, 18 deaths; Provinces, Oct. 9-16, 308 cases, 240 deaths; Oct. 16-23, 256 cases, 202 deaths.

PLAGUE—FOREIGN

China: Amoy, Oct. 8-23, 49 deaths.
Germany: Andreischken, Nov. 7-13, 2 cases; Heydekrug, district, Nov. 18, 1 case.
India: Bombay, Oct. 12-19, 4 deaths; Madras, Oct. 9-15, 1 death.
Japan: Kobe, Oct. 30-Nov. 6, 1 case, 1 death; Moji, Oct. 6-13, 2 cases, 2 deaths; Wakamatsu, Oct. 23-30, 2 cases, 2 deaths.

PLAGUE

Brazil: Bahia, Oct. 14-22, 10 cases, 6 deaths; Pernambuco, Sept. 1-15, 1 death.
China: Amoy, Oct. 9-23, 77 deaths.
India, general, Oct. 9-16, 4,815 cases, 3,992 deaths; Bombay, Oct. 12-26, 24 deaths.
Japan: Kobe, Oct. 16-Nov. 6, 67 cases, 50 deaths; Osaka, Nov. 10, 1 case.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ALABAMA: Montgomery, January 11. Chairman, Dr. W. H. Sanders.
ARIZONA: Phoenix, January 3-4. Sec., Dr. Ancil Martin.
COLORADO: State Capitol, Denver, January 4. Sec., Dr. S. D. VanMeter, 1723 Tremont Place.
DISTRICT OF COLUMBIA: Washington, January 10. Sec., Dr. George C. Ober, 210 B Street., S. E.
ILLINOIS: Coliseum Annex, Chicago, January 19-21. Sec., Dr. J. A. Egan, Springfield.
INDIANA: Room 120, State House, Indianapolis, January 11. Sec., Dr. W. T. Gott.
MINNESOTA: State University, Minneapolis, January 4. Sec., Dr. W. S. Fullerton, 214 American National Bank Bldg., St. Paul.
NEW HAMPSHIRE: State Library Bldg., Concord, January 4-5. Regent, Mr. H. C. Morrison.
NORTH DAKOTA: Grand Forks, January 4-6. Sec., Dr. H. M. Wheeler.
OKLAHOMA: Ione Hotel, Guthrie, January 11. Sec., Dr. Frank P. Davis, Enid.
RHODE ISLAND: Room 313, State House, Providence, January 6-7. Sec., Dr. Gardner T. Swarts.
SOUTH DAKOTA: Sioux Falls, January 12-13. Sec., Dr. F. W. Freyberg, Mitchell.
UTAH: State Building, Salt Lake City, January 3. Sec., Dr. G. F. Harding, 310 Templeton Bldg.
VERMONT: Montpelier, January 11-13. Sec., Dr. W. Scott Nay, Underhill.
WASHINGTON: Spokane, January 4. Sec., Dr. J. Clinton McFadden, 503-5 People's Bank Bldg., Seattle.
WISCONSIN: Milwaukee, January 11. Sec., Dr. John M. Beffel, 3200 Clybourn Street.

Georgia Homeopathic July Report

Dr. R. E. Hinman, secretary of the Homeopathic Board of Medical Examiners of Georgia, reports the written examination held at Atlanta, July 19, 1909. The number of subjects examined in was 12; total number of questions asked, 120; percentage required to pass, 75. Only one candidate, a graduate of Gate City Medical College, 1908, was examined, and he failed, with a grade of 68.8 per cent.

Colorado October Report

Dr. S. D. VanMeter, secretary of the Colorado State Board of Medical Examiners, reports the written examination held at Denver, Oct. 5, 1909. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. Seventeen applicants were examined, of whom 12 passed, including 1 osteopath, and 5 failed. Forty-five candidates were registered on presentation of satisfactory credentials, including state licenses. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
University of Colorado	(1909)	80.7, 85.3
Denver College of Physicians and Surgeons	(1909)	76.6, 77.1, 79.7

Marriages

Harry X. Cline, M.D., to Miss Grace Goodall, both of Marion, Ill., December 7.

Isadore Cohn, M.D., to Miss Millie Siegmund, both of New York City, November 24.

H. Hastings Wyman, M.D., Jr., to Miss Ada Miller, both of Aiken, S. C., November 25.

Augustus Stout Hunt, M.D., to Miss Tossie Mains, both of Jerseyville, Ill., December 8.

Callie A. Rennoe, M.D., to Miss Veronica Starr, both of South Bend, Ind., October 28.

John Henry Ohly, M.D., to Miss Helen Hallowell, both of New York City, November 27.

Melvin John Rowe, M.D., Kalamazoo, Mich., to Miss Derthick of Ionia, Mich., November 25.

Henry Alan Naylor, M.D., Pikesville, Md., to Miss Louise Requardt, at Baltimore, December 3.

John Jacob Rudin, M.D., Galesville, Ill., to Miss Jessie M. Nash, of Mansfield, Ill., November 13.

Royale Hamilton Fowler, M.D., to Miss Lillie Marshall, both of Brooklyn, N. Y., November 24.

Douglas C. Ramsey, M.D., Mount Vernon, Ind., to Miss Rose Shellen, of Evansville, Ind., December 1.

Robert C. Kirkwood, M.D.,, Boykins, Va., to Miss Rose Eleanor Phasey, of Norfolk, November 18.

John W. Turley, M.D., Desloge, Mo., to Miss Lillian Boyd, of Esther, Mo., at St. Louis, November 18.

Henry Frost Hooker, M.D., Danville, Ill., to Miss Nellie McGrath, of Green Bay, Wis., November 25.

James Alexander Harvey, M.D., to Miss Regina Jones, both of Chicago, at New York City, November 30.

Harry P. Shugerman, M.D., U. S. Army, to Miss Eleanor C. Grubb, at Port McHenry, Md., November 8.

Thomas Barnes Futcher, M.D., Baltimore, to Miss G. Marjorie Howard, of Montreal, Que., November 24.

Henry L. Brown, M.D., U. S. Army, to Miss Florella Frederika Lightbourne, of Key West, Fla., November 13.

George Oliver Sharrett, M.D., Cumberland, Md., to Miss Eva Gertrude Basford, at Baltimore, November 24.

Allen Henry Wright, M.D., Stamford, Vt., to Miss Charlotte Frances Park, of Waterloo, N. Y., November 17.

John L. Conover, M.D., to Miss Hattie Eaton, both of North Crandon, Wis., at Menominee, Mich., November 23.

Hugo Abraham Freund, M.D., Detroit, Mich., to Miss Hortense Goldsmith, of Ligonier, Ind., at Detroit, November 9.

Michael J. Shaughnessy, M.D., Wabasha, Minn., to Miss Mae C. O'Brien, of South Framingham, Mass., November 23.

Abraham Nowell Creadick, M.D., Portland, Ore., to Miss Emma Greenwood DeBow, of Philadelphia, Pa., November 23.

William Ellicott Tyson, M.D., Detroit, Mich., to Miss Elizabeth McPherson Weems, at Washington, D. C., November 27.

Thomas Rollins Marshall, M.D., Richmond, Va., to Miss Sue Seddon Taliaferro Wellford, of Gloucester county, Va., at Richmond, November 23.

Deaths

Andrew Caldwell Mailer, M.D. Rush Medical College, Chicago, 1878; Bellevue Hospital Medical College, New York City, 1882; a member of the American Medical Association and National Association of Railway Surgeons; past president of the Fox River Valley Medical Society; local surgeon of the Chicago, Milwaukee and St. Paul Railway at DePere, Wis.; for several years superintendent of the public schools of the city and president of the school board; a member of the state senate from the second district in 1897 and 1899, and twice mayor of DePere; died at his home, December 3, from tuberculosis, aged 56.

William H. Sheets, M.D. Cincinnati College of Medicine and Surgery, 1862; a member of the Indiana State Medical Association; assistant surgeon U. S. Army throughout the Civil War; secretary of the Clark County, Ind., Board of Health; a member of the Jeffersonville Board of Health for twenty years, and formerly ten years city health officer; at one time physician to the Indiana State Prison, South Jeffersonville, and for several years a member of the local pension board; a licensed minister of the Methodist Episcopal church; died at his home, December 1, from tuberculosis, aged 76.

George Zigler Bretz, D.D.S., 1851; M.D. Long Island College Hospital, Brooklyn, N. Y., 1864; major and surgeon in the One Hundred and First Pennsylvania Volunteer Infantry; afterward post surgeon of the Naval Hospital, Plymouth, N. C.; assistant surgeon of the Seventh Pennsylvania Volunteer Cavalry during the Civil War; for five years adjunct surgeon to the Long Island College Hospital; health inspector of Brooklyn, N. Y.; and formerly a member of the Medical Society of the County of Kings; was found asphyxiated by gas in his room in Brooklyn, December 4, aged 84.

Colin Charles Sewell, M.D. University [illegible] land, 1864; McGill University, 1869; [illegible] colonel and surgeon to the Royal Canad[illegible] with active service during the Riel rebellion in 1885; principal medical officer of the Quebec District; a governor of the College of Physicians and Surgeons, Quebec; died at his home in Quebec, December 1, from pneumonia, aged 68. He was given a military funeral and the pallbearers were selected from the officers of the permanent and volunteer corps.

Milton Smith Pixley, M.D. Miami Medical College, Cincinnati, 1866; a member of the Ohio State Medical Association; hospital steward of the Ninety-first Ohio Volunteer Infantry during the Civil War; formerly city physician and a member of the city council and school board of Portsmouth, Ohio; one of the organizers of the Hempstead Academy of Medicine; and secretary of the Scioto County Medical Society; died at his home in Portsmouth, November 29, from cancer, aged 67.

Erasmus Darwin Leavitt, M.D. Harvard Medical School, Boston, 1870; formerly a member of the American Medical Association; a member and first president of the Montana State Medical Association; a pioneer physician of Montana; member of the first two legislatures of the state, and formerly president of the State Board of Medical Examiners; died at his home in Butte, November 30, from carcinoma of the liver, aged 78.

Thomas Griswold Comstock, M.D. Washington University, St. Louis, 1849; Doctor of Midwifery and Master in Obstetrics; Imperial Royal University of Vienna, Austria, 1856; Hahnemann Medical College, Philadelphia, 1851; consulting physician to the St. Louis Free Hospital, and president of the medical staff; physician to the Good Samaritan Hospital; died at his home in St. Louis, December 1, from nephritis, aged 84.

John Perkins Furniss, M.D. New Orleans School of Medicine, 1866; a member of the American Medical Association; a member of the State Board of Censors and Medical Examination; assistant surgeon in the Confederate Service from 1862 to 1865; grand senior life councilor of the Medical Association of the State of Alabama; died at his home in Selma, December 3, aged 68.

Samuel Brightwell Smallwood, M.D. New York University, New York City, 1864; a member of the Medical Society of the State of New York; of Astoria, Long Island City, N. Y.; a member of the consulting board of the New York Eye and Ear Hospital; died in the Post-Graduate Hospital, New York City, November 28, after an operation for ptomaine poisoning, aged 69.

Robert Paine Wendell, M.D. Georgetown University, Washington, D. C., 1892; of Aberdeen, Miss.; a member of the American Medical Association; local surgeon for the Frisco System; was shot, beaten and stabbed to death, November 28, in a hotel in Aberdeen, by a patient who was suffering from alcoholic mania, aged 42.

Frederick Bostock Webb., M.D. University College of Medicine, Richmond, Va., 1901; a member of the Medical Society of Virginia; for several years a missionary in China; since 1902, physician in charge of the Roanoke City Smallpox Hospital; died in the Relay Sanatorium, near Baltimore, December 3, aged 43.

Levin Gillis Owings, M.D. University of Maryland, Baltimore, 1900; of Glenelg, Md.; formerly a member of the American Medical Association; a member of the Medical and Chirurgical Faculty of Maryland; died at the home of his father in Roxbury Mills, November 30, from tuberculosis, aged 33.

Hiram W. Gordon, M.D. University of Pennsylvania, Philadelphia, 1858; formerly a member of the American Medical Association; a member of the Medical Society of Virginia; died at his home in Madison, April, 1908, from cerebral embolism, due to valvular disease of the heart, aged 76.

Pierre A. Banker, M.D. New York Homeopathic Medical College, New York City, 1879; a member of the American Medical Association; excise commissioner-elect of Elizabeth, N. J.; a veteran of the Civil War; died suddenly at his home in Elizabeth, December 2, from angina pectoris, aged 63.

Sophia Presley, M.D. Womans Medical College of Pennsylvania, Philadelphia, 1879; a member of the Medical Society of New Jersey; formerly instructor in surgery in her alma mater; died suddenly at her home in Camden, November 28, from heart disease, aged 65.

David Bennett, M.D. Bellevue Hospital Medical College, New York City, 1866; formerly of Richmond and Lexington, Ky.; at one time president of the National Exchange Bank of Lexington; died in a private sanitarium at Atlanta, Ga., December 2, from gastritis, aged 68.

Junius L. Mann, M.D. Medical College of the State of South Carolina, Charleston, 1901; of Anderson, S. C.; a member of the South Carolina Medical Association; died suddenly at the home of his father in West Union, S. C., November 29, from heart disease, aged 31.

Frank Hickman Matlack, M.D. University of Pennsylvania, Philadelphia, 1872; a member of the Medical Society of the State of Pennsylvania; for twenty years a practitioner of Turtle Creek; died at his home in East End, Pittsburg, November 30, aged 67.

George LeHouillier (license, Mo., 1897); a member of the Florrisant, Mo., Board of Health; for many years house physician to the Loretto Academy and St. Stanislaus Seminary; died at his home, November 25, from rheumatic endocarditis, aged 51.

Henry C. Crowder, M.D. Rush Medical College, Chicago, 1874; a member of the American Medical Association; local surgeon of the Southern Pacific Railway at Tracy, Cal.; died at his home in that city, November 28, from heart disease, aged 65.

Joseph C. Grant, M.D. Kentucky School of Medicine, Louisville, 1896; formerly of Lena, Wis.; a member of the American Medical Association; died at the home of his sister in Livingston Manor, N. Y., November 28, from influenza, aged 40.

Lycurgus Thomas, M.D. University of Tennessee, Nashville, 1907; physician in charge of the Woodward Iron Works, Dolomite, Ala.; died in the city Hospital, Bessemer, Ala., November 25, from typhoid fever, aged 25.

William J. Laird, M.D. College of Physicians and Surgeons, Chicago, 1896; formerly surgeon for the Bay de Noc Company, at Nahma, Mich.; died in Englewood, Chicago, November 15, from pulmonary tuberculosis, aged 45.

Harry Milton Davison, M.D. Western Pennsylvania Medical College, Pittsburg, 1897; formerly of Franklin, Pa.; died at his home in York, Pa., November 22, from acute mania, said to have been due to alcoholism, aged 38.

Franklin Hinkle, M.D. University of Pennsylvania, Philadelphia, 1846; a member of the American Medical Association; assistant surgeon during the Civil War; died at his home in Columbia, Pa., December 2, aged 85.

Stephen Dudley Harrell, M.D. Medical College of the State of South Carolina, Charleston, 1889; a member of the South Carolina Medical Association; died at his home in Lamar, November 29, aged 48.

William E. King, M.D. University of Tennessee, Nashville, 1898; of Lafayette, Tenn.; while riding through the public square of that place, November 27, was shot and instantly killed, aged about 40.

William Augustine Daniel, M.D. Savannah (Ga.) Medical College; a Confederate veteran; died at his home in Jacksonville, Fla., April 7, from chronic hepatitis, due to malarial toxemia, aged 74.

John Clinton Barnes (license, years of practice, Ill., 1877); for forty-four years an eclectic practitioner of Illinois; died in a hotel in Arcola, November 23, from acute nephritis, aged 74.

Micajah Quincy Holt, M.D. Jefferson Medical College, Philadelphia, 1849; of Wakefield, Va.; died in Newport News, Va., November 6, from cirrhosis of the liver, aged 83.

Thomas B. Hicks, M.D. Cleveland (Ohio) Medical College, 1872; died at his home in New Haven, Ill., December 3, from injuries inflicted by an insane patient, aged 68.

Isabella M. Wilson, M.D. New York Medical College and Hospital for Women, 1894; died at her home in Middletown, N. Y., November 30, from pneumonia, aged 58.

Wiley Van Buren Turner, M.D. University of Nashville and Vanderbilt University, Nashville, 1860; died at his home in Greenway, Ark., November 26, aged 75.

Thomas Jefferson Glines, M.D. Dartmouth Medical School, Hanover, N. H., 1853; an eclectic practitioner of Hebron, N. Y.; died at his home recently, aged 82.

Thomas A. White, M.D. Medical College of Indiana, Indianapolis, 1881; died suddenly at his home in Noblesville, Ind., December 3, from asthma, aged 61.

Oscar Green Chamblee, M.D. University of Nashville, Tenn., 1907; of North Birmingham, Ala.; died November 28, at a hospital in Birmingham, aged 26.

Joseph A. Pujos, M.D. Tulane University, New Orleans, 1896; formerly of Schriever, La.; died at his home in Thibodeaux, November 30, aged 47.

John Odie Grove, M.D. University of the South, Sewanee, Tenn., 1904; died at his home in Bradenville, Pa., November 25, from pneumonia, aged 32.

Edward Ayres Russell, M.D. Kentucky School of Medicine, Louisville, 1893; of Butler, Pa.; died in Cambridge Springs, Ohio, November 29, aged 40.

John C. Miller, M.D. Kentucky School of Medicine, Louisville, 1907; of Weeleetka, Okla.; was shot and killed near that place, August 25, aged 29.

Donald A. MacPherson, M.D. Long Island College Hospital, Brooklyn, 1895; died at his home in Brooklyn, November 30, from pneumonia, aged 43.

George W. Nyce, M.D. Pennsylvania Medical College, Gettysburg, 1857; died at his home in Cohoes, N. Y., November 19, from paralysis, aged 74.

James Walker Evans, M.D. Missouri Medical College, St. Louis, 1868; died at his home in Kirkwood, Mo., November 22, from diabetes, aged 63.

John Calvin Cochran, M.D. Barnes Medical College, St. Louis, 1901; of Burkett, Texas; died suddenly in Coleman, Texas, November 23, aged 53.

John A. Fitzpatrick (license, Ill., 1880); of Lemont, Ill.; died in St. Joseph's Hospital, Joliet, Ill., December 1, from hemorrhage, aged 55.

Garnet P. Hyndman, M.D. Michigan College of Medicine and Surgery, Detroit, 1896; died at his home in Minot, N. D., recently, aged 37.

Charles Oscar Hawkins, M.D. New York University, New York City, 1873; of Brooklyn, N. Y.; died in Hoboken, N. J., October 3.

Thomas J. Meek (license, Miss.); died at his home near Courtland, Miss., September 27, from cirrhosis of the liver, aged 55.

Robert S. Brice, M.D. Kentucky School of Medicine, Louisville, 1882; died at his home in Keota, Iowa, November 23, aged 75.

David Zimbleman, M.D. Russia; died at his home in New York City, November 5, from heart disease, aged 32.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

The Duty of the State to the Sick

The following extract from the *Bulletin of the North Carolina Board of Health* for October, is not only of interest as showing the attitude of the health authorities in the South regarding Mr. Rockefeller's gift of $1,000,000 for the extermination of the hookworm disease but also contains several points which may be of value to those interested in the campaign for better health conditions in other states:

ONE MILLION DOLLARS' WORTH OF STOCK IN PUBLIC HEALTH

On the 26th of October a man whom all the world recognizes as one of the shrewdest business men that ever lived decided to invest one million dollars in public health.

This unprecedented investment should suggest to the public mind several interesting and significant inquiries: *First,* did Mr. Rockefeller put a million dollars in something that will not bring the desired returns? *Second,* did Mr. Rockefeller invest one million dollars in something theoretical, something nothing more than the dream of an idealist, something impracticable? Did this shrewd, calculating business man, for once, disregard all precedent and invest this sum of money without thoroughly investigating the value of his investment? Judging from his letter, he did not, for in this letter he says: "For many months my representatives have been inquiring into the nature and prevalence of "hookworm disease" and considering plans for mitigating its evils. I have delayed action in this matter only until *the facts as to the extent of the disease could be verified and the effectiveness of its cure and prevention demonstrated.*" (The italics are ours.) It is therefore apparent that Mr. Rockefeller did not take any one's word for the loss of health and life from hookworm and the practicability of its cure. He made his own investigation, and arrived at results that justified this reckless (?) investor in putting up one million dollars for the sanitary war against hookworm.

Now, scientists have for several years been claiming just what Mr. Rockefeller "verified" and "demonstrated," and, on these claims they have urged state governments to appropriate money for the preservation of such a cheap thing as human health and life. On the other hand, state governments, judging from their appropriations for different purposes, have considered it better business to spend the state's money on trees, plants, animals, birds, etc., as is well illustrated by the following story:

The Young Mother and the Fat Hog—Not a Fable; Simply Straight Goods

One time a little mother, who was only twenty-five years old, began to feel tired all the time. Her appetite had failed her for weeks before the tired feeling came. Her three little girls, once a joy in her life, became a burden to her. It was "Mamma," "Mamma," all day long. She never had noticed these appeals until the tired feeling came. The little mother also had red spots on her cheeks and a slight dry cough. One day, when dragging herself around, forcing her weary body to work, she felt a slight but sharp pain in her chest, her head grew dizzy and suddenly her mouth filled with blood. The hemorrhage was not severe, but it left her very weak. The doctor she had consulted for her cough and tired feeling prescribed bitters made of alcohol, water and gentian. This gave her false strength for a while, for it checked out her little reserve. When the hemorrhage occurred, she and all her neighbors knew she had consumption, and the doctor should have known it and told her months before.

Now she wrote to the State Board of Health and said: "I am told that consumption in its early stages can be cured by outdoor life, continued rest, and plenty of plain, good food. I do not want to die. I want to live and raise my children to make them good citizens. Where can I go to get well?" The reply was: "The great Christian State of Indiana has not yet risen to the mighty economy of saving the lives of little mothers from consumption. At present, the only place where you can go is a grave. However, the state will care for your children in an orphan asylum after you are dead, and then in a few years, a special officer will be paid to find a home for them. But save your life—never. That is a cranky idea;" for a member on the floor of the Sixty-first Assembly said so. "Besides," said he, "it isn't business. The state can't afford it." So the little mother died of the preventable and curable disease, the home was broken up, and the children were taken to the orphan asylum.

A big fat hog one morning found he had a pain in his belly. He squealed loudly and the farmer came out of his house to see what was the matter. "He's got the hog cholery," said the hird man. So the farmer telegraphed Secretary Wilson of the U. S. Agricultural Department (who said the other day he had 3,000 experts in animal and plant diseases), and the reply was: "Cert., I'll send you a man right away." Sure enough, the man came. He said he was a D.V.S. and he was, too. He had a government syringe and a bottle of government medicine in his handbag, and he went for the hog. It got well. It wasn't cranky for the government to do this, and it could afford the expense, for the hog could be turned into ham, sausage, lard and bacon. Anybody, even a fool, can see it would be cranky for the state to save the life of a little mother, and it could not afford it, either.

MORAL: Be a hog and be worth saving.

(The background of this story is laid in Indiana, but its truth applies with equal force to our own state. For while Indiana is spending $43,500 annually on her public health, North Carolina is spending the extravagant sum of $8,500 annually on our public health.)

Now, from what has been said, it is very evident that there exists a very great difference of opinion between John D. Rockefeller and the average state government as to the value of public health. Either one or the other has made a big mistake, and if the oil king has made a bad business move, it is about his first one. Whatever many people may think of his business methods, it would be rather difficult to find a sensible person who questions his business sense.

It is believed this gift will serve its chief purpose, not in the eradication of hookworm, which it will to a large extent accomplish, but as a demonstration to state governments of the value of human health and life. And when that good day arrives, legislatures will investigate and verify the unanimous conclusion of scientists and statisticians, namely, that our country is losing 250,000 lives or their equivalent, $400,000,000 from sickness every year. Then in a great sanitary war against preventable disease, state governments will honor John D. Rockefeller by following his lead.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fourth Month—Fourth Weekly Meeting

Treatment of Pelvic Inflammation

Non-Surgical: General: Local, douche, tampon, massage, etc.

Surgical: Routes of Operation.—Abdominal section, technic of removal of appendages, of salpingo-oöphorectomy. Technic in (a) pus cases, (b) in adhesions, (c) in hemorrhage, (d) in intestinal opening. Indications and technic in abdominal hysterectomy.

Vaginal Section: Indications for (a) posterior, (b) anterior vaginal section. Technic of vaginal hysterectomy by (a) ligature, (b) forci-pressure. Indications for vaginal incision and drainage. Relative advantages and disadvantages of abdominal and vaginal routes.

Monthly Meeting

Diagnosis and Treatment of Tuberculous Salpingitis.
Indications and Contraindications for Curettage.
Diagnosis of Pelvic Inflammation.

Fifth Month—First Weekly Meeting

General Subject for the Month: Diseases of the Stomach, Intestines and Pancreas

Anatomy

Surface Anatomy: Stomach, cardiac and pyloric orifices, curvatures. Small intestine. Large intestine. Cecum and appendix, ascending, transverse and descending colon, sigmoid. Pancreas.

Gross and Microscopic Anatomy: Stomach. Important relations. Structure, serous, muscular, submucous and mucous coats. Glands, cardiac and pyloric. Blood-vessels, lymphatics and nerves. Small intestine. Duodenum, jejuno-ileum, length, relations, limits, diameters, mesenteric attachments, blood-vessels, nerves and lymphatics. Structure, serous, muscular, submucous and mucous coats. Valvulæ conniventes, villi crypts of Lieberkühn, Brunner's glands, lymph follicles. Large intestine. Portions, length, diameters, mesentery. Characteristics, bands, sacculations, appendices, epiploicæ. Difference in structure from small intestine. Blood-vessels, lymphatics, nerves. Pancreas. Location, length, size, portions, ducts, microscopic structure, blood-vessels, lymphatics.

Physiology of Digestion

Mastication and Salivary Digestion

Gastric Digestion: Effect of pepsin and hydrochloric acid, of rennin. Effect on other foods. Absorption from stomach. Movements of the stomach.*

Intestinal Digestion: Pancreatic secretion, composition, three enzymes, secretin and mechanism of pancreatic secretion, enterokinase, effect of each enzyme in digestion. Succus entericus, enzymes present and functions of each. Intestinal movements, peristaltic and pendular. Absorption from intestine of carbohydrates, of fats, of proteins. Digestion and absorption in large intestines.

REFERENCE BOOKS FOR THE FIFTH MONTH

Hemmeter: Diseases of the Stomach and Intestines.
Boas: Diseases of the Stomach; of the Intestines.
Einhorn: Diseases of the Stomach and Intestines.
Nothnagel's Practice.
Opie: Diseases of the Pancreas.
Billings: Diseases of the Digestive Tract.

Society Proceedings

COMING MEETINGS

American Physiological Society, Washington, D. C., December 28-30.
Medical Society of State of New York, Albany, January 25.
Western Surgical and Gynecological Assn., Omaha, December 20-21.

AMERICAN ACADEMY OF MEDICINE

Third Mid-Year Meeting held at New Haven, Conn., Nov. 11-12, 1909

CONFERENCE ON PREVENTION OF INFANT MORTALITY

(Continued from page 2028)

The Relation of Syphilis to Infant Mortality

Dr. Richard A. Urquhart, Baltimore: Of all the grave consequences following on this one of the modern plagues, none are so serious as those of heredity. The high rate of infant mortality among the children of such parents is its greatest social danger. Many others, fortunate or unfortunate enough to survive its first effects, grow into a weakling childhood and manhood. a misery to themselves and a public charge. Few greater problems offer themselves to the philanthropist, to the social worker, the teacher and the state. The false position assumed toward social diseases by the authorities and the consequent ignorance of the far-reaching effect of such diseases is an everlasting disgrace to our modern civilization. It is high time that physicians, knowing its perils, force on the powers that be the right of the public to protection, as in the case of any other contagious disease. The details of the required laws and methods of making them efficient will work themselves out. It is not merely prohibiting a fool from his folly; frequently the innocent suffer; the state has to support weaklings, and racial degeneracy results.

DISCUSSION

Dr. Helen C. Putnam, Providence, R. I.: Syphilis should be placed among the reportable diseases.

Dr. R. A. Urquhart: In view of the dread of publicity felt by persons suffering from syphilis, there is danger that they would not seek medical aid, and the result would be worse than if there were no report.

Dr. J. Morton Howell, Dayton, Ohio: One solution of the problem would be the introduction of courses of lectures by the medical inspectors into the curricula of boys in high schools.

The Curative Powers in Human Milk

Dr. J. Madison Taylor, Philadelphia: Scientific substitute infant feeding, primarily a boon, often proves a peril. Physicians are lulled into a false sense of security and too readily allow mothers to omit breast-feeding. Mothers, both rich and poor, too often assume that it is just as well to use the bottle, thus imperiling life and health, and especially right constitutional development. Sifting the evidence emphasizes (1) the well-known but inadequately realized fact that breast-feeding is of paramount value, not only as a food, but as contributing to prevention and cure of infectious and other diseases; and (2) the testimony from physiology as to the curative powers residing in the autoprotective qualities of the serum of milk, especially human milk.

Excessive Child-Bearing as a Factor in Infant Mortality

Dr. Alice Hamilton, Chicago: This paper embodies the results of a statistical study of 160 families with regard to the number of children born and the number who died at birth, in infancy or in early childhood. The families selected were almost all from the poorer wage-earning class, the parents being foreign born in all but 3 per cent. Families with 6 children and over were placed in one group, those with 4 children and less than 4 in another group. The percentage of child mortality in the first group was over two and one-half times that in the second group. As the nationality, economic standing, mode of life and knowledge of infant hygiene was the same for the two groups, the explanation of this great mortality in the larger families lies probably in the insufficient care given to the over-numerous children and in the exhaustion of the mothers through excessive child-bearing. Grouped according to nationalities, the Jews show the lowest child death-rate, with the American-born next; the Italians the highest and the Germans, Irish and Slavs ranging in between in the order named.

---

* Howell: Physiology, 2d Edition, p. 661.

DISCUSSION

Dr. T. Smith, Worcester, Mass.: I have made a study of the mortality among the wives of college graduates, Yale and Harvard graduates, going back 200 years, and have found that 33 per cent. died before they were 35 years old. I discovered also, in tracing out the records of some of the old New England families for a number of generations, that the large families seemed to tend to be extinguished by the fourth or fifth generation. For example, in one family, there were 20 children; 8 by the first wife and 12 by the second, but there are now no living descendants except through one son. In a second family of 10 children, the mother died at the age of 40. Of the 10 children, the 3 youngest were invalids; 2 lived to the age of 30; 8 married. Of these marriages there are only 3 descendants surviving.

The Waste of Infant Life

Dr. Edward T. Devine, New York: It is sufficiently obvious that the enormous waste of infant life is a social problem of fundamental importance. Just how enormous the waste is we cannot exactly determine. It begins with the abortions and miscarriages which have been estimated to be the end of one pregnancy out of every five. It includes next the children born dead, though at full term, which happens, as nearly as we can tell, in about one case in twenty-eight. And the total is made up by the great numbers of babies born alive who die before they reach the age of 1 year. In New York one-seventh of all the babies born die before they are a year old, and their deaths make up between one-fifth and one-fourth of the total mortality. An encouraging decrease can be seen in New York in the last forty years. Between the decades 1866-75 and 1896-1905 the infant death-rate decreased 43 per cent., while the general death-rate decreased only 26 per cent. In spite of this decrease it is the opinion of the medical experts that a large part of the infant deaths which now take place are preventable. The social economist adopts the medical expert's opinion, and it is his part to devise means for preventing that part of the preventable waste which is due to adverse social conditions. "Prevention of infant mortality" is the subject of the conference, but that is not the ultimate object. The phrase is symbolic, suggestive, for the important thing is not merely to prevent babies from dying, but to keep them well and increase their strength, to give them the best possible beginnings for their lives. The efforts which give promise of the best and quickest returns are those which will decrease the proportion of premature and immature babies born, and will increase the proportion who are fed properly through their first year.

The Relation of Race to Infant Mortality

Dr. Richard C. Cabot, Boston: This paper embodies the results of an examination of the vital statistics of Boston. Three thousand two hundred and ninety certificates of the board of health were studied for three wards of the city—one almost entirely Jewish, a second almost entirely Italian and a third almost entirely Irish. Excluding premature births and stillbirths, the infectious, diarrheal and digestive diseases make up about one-half of the total figures and the stillborn cases one-fifth; the premature and stillborn combined, about one-third. The mortality from pneumonia and tuberculosis represented more than two-thirds of the total mortality from all the infectious diseases reported to the board of health. In spite of the fact that the Jewish race is not supposed to be especially prone to alcoholism and syphilis, it was found that the proportion of stillbirths in Jewish families was 64 per 1,000 births; Italian, 41 per 1,000; Americans and Irish, lower. In birth accidents and in digestive diseases, the figures for the Jewish race were in the lead. The mortality from digestive diseases, excluding infectious diseases, was 54 per 1,000 births among the Jewish families; 35 per 1,000 among the Irish; 31 among Italians and 29 among Americans.

A Program for the Reduction of Infant Mortality in New York City

Mr. Robert W. Bruère, general agent of the New York Association for Improving the Conditions of the Poor: The problem of infant mortality in New York City is primarily a problem of poverty. This statement is based on the records of the New York Department of Health. The evolution of the campaign against infant mortality among the poor is illustrated by the work of the New York Association for Improving the Condition of the Poor. There are fresh-air pleasure parties at Sea Breeze, Coney Island. Sea Breeze has been partially changed from a picnic ground into a summer convalescent home and school for mothers. Summer district work has been started at Junior Sea Breeze in the heart of the city. All-year-round follow-up work has been inaugurated in connection with children's dispensaries, and infants' milk depots have been established by the New York Milk Committee. Impure milk and low wages are factors in determining the infant death-rate.

In view of the fact that 46 per cent. of the workers in New York receive less than $10 a week or $300 *per annum*, less than the sum given in the report of the Committee on the Standard of Living prepared by the New York Conference of Charities and Corrections and published by the Sage Foundation, as necessary to keep body and soul together, there should be a system of compulsory sick insurance, similar to that in practice in Germany. This insurance should be contributory; part provided out of the general taxation, and to a lesser extent out of the premiums paid by policy holders. The insurance should be compulsory for all persons with incomes less than $1,000 a year.

Educational Responsibilities of a Milk Depot

Dr. Ira S. Wile, New York: The educational possibilities of a milk depot are the only limits to its educational responsibility. Its possibility is that of making milk depots unnecessary institutions. Its function should not be merely to supply a milk for infant feeding, but at least to teach mothers why it is supplied. Its responsibility is three-fold: to the infant, to the family, to the community. To the child the responsibility of the milk depot lies in attempting to supply a proper milk, i. e., its own mother's milk. An index of the value of a depot lies in the number of nursing mothers visiting it; not in the amount of modified milk sold. At each depot there should be a museum to exhibit all that relates to child hygiene from the prenatal period to the school period. To the family the depot is responsible for teaching the whole household how to keep the children well—not merely how to avoid letting them die. There should be classes for "little mothers" and expectant mothers, as well as for mothers with children. Toward the community the depot has the responsibility of developing mothers capable of bringing up their children to maturity, and of destroying the possible element of truth in the statement that children grow up in spite of their parents, not by means of them.

The Responsibilities of General Relief Agencies in Prevention of Infant Mortality

Mr. Sherman C. Kingsley, superintendent of the United Charities of Chicago: The particular responsibility of relief agencies lies in the fact that their work is in the very homes where babies die in largest numbers. Our philanthropy and our municipal housekeeping ought to be brought to this test: Do they furnish conditions that are right for the baby? Where the white hearse goes most often, there you will find the weakest places in your municipal housekeeping. The charity organization society, or similar agency, is the natural agency to arouse public interest in the question of infant mortality in a city where it has received scanty attention. In such a place it will probably run afoul of the question of registration of births, of general insanitary conditions, of the problem of desertion, of the problem of the registration of midwives. There are also certain pressing and immediate responsibilities resting on charitable organizations in connection with their own special work: they should not send pregnant women to wash and scrub; they should make possible a reasonable period of convalescence after the baby is born; they should see to it that the family lives in rooms consistent with health for the baby; they should not encourage a mother to wean her baby in order to go back to work; they should see to it that the mother herself is properly nourished; they should continue the visits of the nurse until the mother has profited by her instructions; they should be more patient in winning the confidence of the foreign mothers and teaching them. The conclusion of the whole matter may be suggested in the homely annals of one baby who died: begotten of a father who deserted before the baby came; born in an insanitary, three-room tenement house; attended by a midwife, who was unlicensed and ignorant; unrecorded in the city's book of births; suffered on account of feeding which was in accordance with the traditions of its mother and because she had to earn a living; died without ever having had a drink of water; furnished with a funeral that further impoverished the family.

Results of Philanthropic Experiments in Increasing and Decreasing Infant Mortality

Dr. Woods Hutchinson, New York: The progress of civilization has markedly diminished infant mortality, but not at so great a rate as other mortality. The institutional treatment of infants is almost entirely a failure. There is no place like home for growing live children. The chief causes of infant mortality are poverty with its children, ignorance and dirt. The cure is higher wages and shorter hours. Cheap food is usually deficient in nutritive value. Nursing mothers and children must have expensive foods. Any effort helping mothers to work instead of nursing their babies is a mistake. Prizes for large families are a mistake. The death-rate is high in families too large to be properly cared for.

Institutional Prevention of Infant Mortality

Mr. Homer Folks, secretary of the New York State Charities Aid Association: In institutions for providing a home for presumably well infants, mortality has always tended to be very high. Of 28,436 babies received at the St. Petersburgh Foundling Hospital, 24,272 died, 85 per cent. In such institutions mortality has been reduced, but is still excessively high, not more than 50 per cent. surviving among the best institutions. This is not from neglect. Artificial feeding kills babies in infant homes. Babies and their mothers should be kept together. Hospitals for sick babies are necessary and valuable.

Providing Situations for and Otherwise Assisting Homeless Mothers with Their Infants

Miss Mary R. Mason, agent of the Committee on Assisting and Providing Situations for Mothers with Infants, New York City: The death-rate is frequently from 90 to 100 per cent. when babies are separated from their mothers. Agencies find it entirely practicable to place women with babies in domestic service, chiefly in the country or small towns, with wholesome environment. Increasing stringency in the domestic service market increases desirable opportunities. The Philadelphia Society, 1908, placed 609 mothers. In 15 years the New York Agency has provided over 7,000 situations. Statistics are difficult to present, as the situation is usually only temporary (until father obtains work, or families are reconciled; many widowed or unmarried marry). In three years (1900-1902) of the mothers kept track of, four-fifths of the babies lived and were in good condition; one-fifth died or were in poor condition. Agencies need closer cooperation with maternity hospitals to induce mothers to keep, not abandon their babies; more temporary homes; more places for training incompetent mothers. The plan of keeping mothers and babies together is susceptible of much wider application.

DISCUSSION

Mr. E. D. Solenberger, Philadelphia, approved of the placing-out system, but recommended that a most careful and discriminating examination be made by the hospital physician of mother and child before sending out to a situation; and emphasized the need for greater cooperation between hospitals and similar institutions and the child-placing organizations. Statements of physicians and their recommendations as to the character of the work women were fitted to do, would be accepted by employers as authoritative, and would prevent them from giving too heavy manual work to women physically unable to perform such duties. Hospitals, on the other hand, would be more willing to care for a woman through a longer period of convalescence, knowing that the child-placing association would at the end of the time have a situation ready for the woman.

Dr. J. H. Mason Knox, Jr., Baltimore, commended the placing-out system, but said that in view of the fact that a great many children are still being cared for in institutions legislation should be enacted which should secure adequate care, the necessary amount of air space and a sufficient number of attendants for the children now in institutions. He took exception to the statement that practically all infant mortality in institutions was due to artificial feeding. That this is only partially true, he said, is shown by the fact that among the wealthier classes only a small proportion of the artificially fed babies die when they have the proper food and the necessary care. There are hundreds of asylums in our large cities which are practically death traps, not primarily because they are asylums, but because they fail to do their whole duty to the child. Inadequate care, too few nurses, in many instances an inefficient nurse maid in charge of 20 or 30 babies, instead of a trained nurse caring for 3 babies; insufficient air space, large wards with 30 or 40 babies in one room, instead of 3 or 4 babies in separate quarters, he declared to be responsible for some of the excessive mortality in institutions. These are conditions, he said, not theories, and since there is no chance that institutional care can for the present be disregarded, he urged the insistence on remedial legislation by states and health departments to make the care more adequate to the recognized needs of the child.

The Care of Infants Apart from Their Mothers

Dr. Charles P. Putnam, Boston: Foundling Hospitals are charitable in aim. The Massachusetts Infant Asylum may be used as an object lesson. For ten years it cared for all the state babies. One-half of the first 300 died. Babies are received no matter how ill. More complete investigation and cooperation by paid officers makes more admissions and sicker babies. Of the first 1,000 cases, 530 were legitimate, 470 were illegitimate and 69 were taken for adoption. No babies have been taken for adoption during the past 30 years. Of the first 1,000, 21 mothers deserted, but in the last 500 there were only 2 possible desertions. Of the first 2,000, 377 babies given away in adoption. Now the policy is quite opposite. Only those are admitted who do not properly belong elsewhere. The boarding-out system now requires the whole time of two trained nurses. Mothers are required to visit frequently. Parents and others must pay. 1. If mothers cannot be kept with babies, their interest must be kept with them. 2. This keeps as mothers' babies many that otherwise would be thrown on the public. 3. Many mothers who would have lost a bond to society now retain it.

The Care of Infants Who Must be Separated from Their Mothers Because of Some Especial Need on the Part of the Child

Dr. Emelyn Lincoln Coolidge, New York: It is a serious matter to separate a mother and her child, especially if the baby is breast-fed; but sometimes this is necessary if the mother is too poor and ignorant to care for the baby at home. Babies' hospitals are valuable for the treatment of infants who are very ill with some acute disease. If a baby cannot be nursed by its own mother and there is difficulty in feeding it artificially, it would be well to board the child with a reliable wet nurse who is under the control of a babies' hospital. Babies sick or well need individual treatment, as well as scientific and skilful care. There should be enough nurses in every hospital for babies so that they will have time to hold the patients, at least occasionally, giving them the individual attention which is many times their salvation. The patients in a babies' hospital should not only be looked on as "interesting cases," but as babies absolutely dependent on conscientious and tender care. Physicians and nurses who are to have the care of infants need special training in this particular branch of medicine. Those who graduate from a general hospital or college are not competent to assume the care of sick infants without first devoting considerable time to conscientious study of the diseases of infancy and childhood. In a babies' hospital small wards are desirable, ten or twelve beds in each ward being about the right number. If contagion then breaks out the ward may be isolated and the disease checked at the start. Plenty of fresh air and sunlight must fill all the wards.

DISCUSSION

Dr. H. J. Gerstenberger, Cleveland: An effort should be made in every city to have a babies' hospital, which should serve also as a school for the training of physicians, nurses and midwives, and which should offer post-graduate courses and furnish opportunity for research work.

Dr. J. H. Mason Knox, Jr., Baltimore: I do not consider a preliminary examination of a child before admission to a ward sufficient; the plan of many hospitals of keeping a baby in a retention room, under careful supervision, for forty-eight or seventy-two hours before admitting to the general ward, is a more effective precautionary measure than the preliminary examination alone. In the placing-out system, there is great need for careful examination of mother and child before sending out to situations or into homes. In one case a family was persuaded to take a child which was supposed to be perfectly healthy. As a result, syphilis was contracted by two members of the family which befriended the child. Owing to the difficulty in diagnosing the disease in very young infants, until the lapse of six weeks or two months at least, the placing-out system, while excellent, should not go into effect until after a certain length of time, and not until the most careful laboratory and clinical diagnosis had been made. Speaking of the work of the milk stations, the importance should be emphasized of having not only trained nurses, but of having nurses especially trained in the care of children who would give their entire time, in connection with the work of the milk station, to babies and young children, and to the instruction of the mothers.

Mrs. Mary Kincaid, New York, outlined the work of the *Delineator* in forming mothers' conferences, first in New York, and then throughout the country.

Dr. Albert Hale, Bureau of American Republics, Washington, spoke of the methods by which the infant mortality in Buenos Aires, Argentina, has been reduced to such an extent that the city has one of the lowest infant death-rates in the world. The reduction was brought about largely by means of reforms instituted by the municipality, among them the control of the milk supply, the control of the water supply and the installation of a drainage system at a cost of $50,000,000. Another factor in the reduction of infant mortality is what is known as the *assistencia publica*, which maintains laboratories, and which is educational also.

Assisting Mothers in the Care of Sick Infants in Their Own Homes

Miss Lillian D. Wald, Nurses' Settlement, New York City: An important factor in lowered infant mortality is the skilled district nurse who gives serious nursing care in the homes viz.: The daily thorough bathing, the antiseptic care of mouth, nasal passage, eyes and external excretory organs; application of medical treatment, of hydrotherapy, dressings, etc.; who keeps records and makes observations, teaches the members of family how to ventilate, prepare diet, maintain the best available surroundings, and who secures the use of all necessary equipment and appliances for comfort of the patient. An illustration of the value of such service is given by the figures of the settlement of pneumonia and bronchitis in children whose ages ranged from 2 weeks to 2 years, these figures covering only three months' time. Total number cases pneumonia and bronchitis, 156, divided as follows: Lobar pneumonia, 64 patients (died, 9; sent to hospital, 4; cured, 51); bronchopneumonia, 84 patients (died, 6; sent to hospital, 24; cured, 54); pleuropneumonia, 8 patients (died, 2; sent to hospital, 6); bronchitis, 11 patients (sent to hospital, 2; cured, 9). During the same three months there were cases of intestinal disorder of various kinds, diarrhea, dysentery, enteritis, malnutrition, colitis, thrush, etc., etc., in children of the same ages. Total, 72 children: (sent to hospital, 11; died, 7; cured, 54). Hospital cases were usually complicated by some infectious disease. The pneumonia cases were in the large majority of cases of marked severity. Many of the intestinal cases also were serious and required most careful management.

(*To be continued*)

Book Notices

Infinity or Nature's God. By F. J. Duggan, M.D., Grand Forks, N. D. Flexible Leather. Pp. 136. Price, $1.50.

If the unconscious be the highest type of humor, then in this book we have something that will inevitably add to the gaiety of nations. Not that it is written with any such intent; the author takes himself and the universe far too seriously to be guilty of perpetrating a joke intentionally. The reader is informed in the preface that this work is "a prose composition, poetic in form and scientific in character." It was written "under the impulse of an irresistible influence" while the author was "in a pleasant semiconscious reverie." Still further to divide the parental responsibility for this epic, the author states that a "strange muse, whose promptings made the task easy" is really the being "who must, most assuredly, be held responsible for the existence of the poem." In closing the preface and foreseeing the effect that his verse may have on those whose mentality is not the most stable, the author expresses the hope "that detention hospitals may be established in every county in the land for the treatment of incipient insanity." The poem begins at the Beginning. Of the creation of matter we read:

> "Ever was and is to be," describes the situation.—
> The technical terms, wrongly used, were for elucidation.

Matter having been satisfactorily accounted for, a description of the natural forces seems rational. For instance, a tornado in the author's town:

> . . . . sweeps down the street,
> With planks, chairs, and debris dancing on its spray four feet deep;
> Tin roofs, whole blocks of sidewalk are flying in the air,
> With small houses scattered to the wind my heart despairs.

Much havoc was wrought, apparently, for we read that there were

> Three killed, many injured, the train from off the track was blown;
> This certainly was the swiftest storm that ever I have known.

But it is when that mystery of mysteries—life—is touched on that the sublimest heights are reached.

> Who views the fishy tadpole would connect him with the frog,
> Anxious watching o'er his progeny while sitting on the log?
> Who sees the wriggling wiggler in the rain-barrel, ne'er at rest,
> Can see yellow fever and ague in the mosquito pest?

Nor is therapeutics forgotten; quinin is apostrophized thus:

> The parasite, the hematozoon at home in human blood,
> Is poisoned by the Jesuit-bark; it killed him where he stood.

These quotations must suffice. To analyze the entire work would require much time—and paper. As its author says, "it is readily seen the immense possibilities attending such a work." The book "was not written for remuneration" and must be read to be fully appreciated.

A Text-Book on Practical Obstetrics. By Egbert H. Grandin. A.B., M.D., Gynecologist to the Columbus Hospital. With the Collaboration of George W. Jarman, M.D., Gynecologist to the General Memorial Hospital and Simon Marx, M.D., Late Surgeon to the New York Maternity Hospital. Edition 4. Cloth. Pp. 538, with illustrations. Price, $4.50. Philadelphia: F. A Davis Co., 1909.

This edition has been revised by Dr. Simon Marx. It aims at the greatest possible directness in the statement of clinical facts and omits all anatomic, embryologic and pathologic data that are not essential. It omits all literature reference and statistical data except such as are necessary to elucidate disputed facts. Brevity, accuracy and practicability, with the avoidance of theory and hobby, are the aims striven for by the authors.

These objects have been attained with a fair degree of success and the revision has much improved the book. Certain defects have escaped the reviser. In Chapter 4 the definitions and usage of the terms "presentation," "position" and "attitude" are confused and incorrect, as for example, when the position is said to be transverse or the attitude of the fetus is transverse or longitudinal. Figure A in Plate VIII, showing the method of making abdominal palpation at the pelvic brim, is incorrect. The hands should press into the sides so as to grasp the head or presenting part instead of pressing it back. On page 152, the definition of the pelvic outlet is mistakenly given for that of the "inferior strait." On page 154, in the description of the attachments of the levator ani, it is said that this muscle is attached to the lateral walls of the vagina and to those of the bladder, a statement quite contrary to the fact. On page 159 it is correctly stated that "under normal conditions the head does not become perfectly flexed until the membranes have ruptured," then is added the obscure and incorrect statement "that is to say, descent does not begin." It is impossible to understand why Plates 23, 24 and 25, showing ungowned assistants and flexion maintained by the bare finger in the rectum, should be retained. Very few nurses would be willing to adopt the advice on page 244 to bathe the infant in water at the temperature of 80 to 90. The advised treatment of puerperal endometritis and metritis by thorough examination and intrauterine injections and curettage is opposed to the views of most modern teachers.

These faults should not disfigure a modern work on obstetrics. Their presence indicates too low an estimate of the critical demands of modern teachers of obstetrics. A greater thoroughness in the revision should have eliminated them and have left a book that would merit high commendation for its laudable aims and valuable contents.

Rational Immunization in the Treatment of Pulmonary Tuberculosis and Other Diseases. By E. C. Hort, B.A., B.S.C., M.R.C.P. Cloth. Pp. 75, with illustrations. Price, $1.50. New York: *William Wood & Co.*, 1909.

The main motive in this publication of seventy-five pages appears to be the belief that those interested in immunization, particularly vaccine therapy, do not take into sufficient consideration the possibility that disturbed enzymic action of the body cells is responsible for much of the injury which attends infections. So far as can be gathered from the somewhat involved phraseology, the assumption appears to be made that in health the enzymes of the body are held in equilibrium by antienzymes, and that in infections this equilibrium is disturbed; that the antienzymes appear to be ineffective or deficient as a consequence of bacterial action; and that this state of affairs leaves the autolytic, and perhaps other enzymes free to injure the cells of the body. On the basis of this assumption, which the author appears to accept as a fact, he deplores that we do not immunize with enzymes and emulsions of the body cells as a means of causing the further formation of antienzymes, to the end that the pernicious action of the enzymes during infection may be antagonized.

After considering briefly the subject of vaccination with cultures of bacteria (hetero-inoculation) the subject of autoinoculation is discussed. Counter-irritation, Bier's methods, active and passive movements, light and heat, respiratory exercises, radium and *x*-rays, and high altitudes, are cited as means of producing autoinoculation artificially. In such procedures, Hort believes, the micro-organisms become more or less disseminated and stimulate the formation of antibodies.

The author prefers the method of autoinoculation whenever practicable, because, in addition to causing the formation of bacteriotropic substances, it also causes the production of those substances which inhibit the pernicious activities of the body ferments. The data cited to justify the latter conclusion are far from convincing in character. The unusual position is taken that the temperature curve is a measure of the process and extent of immunization. The opsonic index is considered as an unreliable indicator of the state of the patient's resistance.

In conclusion the author states: "Full conviction I can hardly hope to carry on the slender evidence here produced, but the attempt will not be fruitless if the attention of the makers of modern medicine be for the moment diverted to issues other than the merely bacterial."

Obstetrics. A Manual for Students and Practitioners. By David James Evans, M.D., Lecturer on Obstetrics and Diseases of Infancy, McGill University, Montreal, Canada. Second Edition. Cloth. Pp. 440, with 172 illustrations. Price, $2.25 net. Philadelphia: Lea and Febiger, 1909.

In this edition of Evans' "Obstetrics," several changes have been made and certain sections rewritten. The book is now one of the best of the smaller works on the subject; it is scientific and shows the mature judgment of a large and clear observation. The various subjects are presented in a concise manner with due regard to the relative importance of the various divisions.

In the presentation of some of the debated questions of obstetrics the author in a few instances adopts views that some would criticize as insufficiently established or antiquated. For example, Williams' classification of pernicious vomiting of pregnancy into toxemia and other forms which can be distinguished by the urine examination is hardly so well established as to form an indication for treatment of the former by such a radical method as the induction of abortion.

On the other hand no well-authenticated evidence authorizes attributing "congestion or engorgement" of the breasts to exposure to cold and hypersecretion of milk. The treatment of this condition with massage, the breast-pump and pressure bandage does not furnish as satisfactory results as the more simple and rational methods of support and the application of cold. The indication for abortive treatment of mastitis, to secure complete rest for the affected gland, would prohibit the use of the second method, namely, removal of the contents of the gland by means of massage and the breast-pump. So also the arrest of lactation by compression of the breast, purgation, and the restriction of fluids ingested, the use of massage and the breast pump and the application of glycerite of belladonna is not only pretty well-known to be unnecessary, but needlessly meddlesome and unpleasant, if not harmful.

American Practice of Surgery. A Complete System of the Science and Art of Surgery, by Representative Surgeons of the United States and Canada. Edited by Joseph D. Bryant, M.D., LL.D., and Albert H. Buck, M.D. Complete in Eight Volumes. Volume VI. Cloth. Pp. 916, with 624 text illustrations, and 39 plates. Price, $7. New York: *William Wood & Co.*, 1909.

Volume 6 of this work, the previous volumes of which have already been mentioned in these pages, treats of "Prothesis in its Relation to Surgery of the Face, Mouth, Jaws and Nasal and Laryngeal Cavities," "Surgical Diseases and Wounds of the Nasal Cavities and Accessory Sinuses," "Surgical Diseases and Wounds of the Mouth, Tongue and Salivary Glands," "Surgical Diseases and Wounds of the Neck," "Surgical Diseases and Wounds of the Thyroid and Thymus," "Surgery of the Thorax and Spinal Column," "Surgical Diseases and Wounds of the Female Breast," "Surgical Diseases and Wounds of the Genitals and Vagina of the Female," "Surgical Diseases and Wounds of the Male Genital Organs," and "Chancroid, Gonorrheal Urethritis, Surgical Diseases and Wounds of the Jaw."

Some of the subjects are so comprehensively handled that the chapters amount to real monographs, thus making this volume of great value to the specialist as well as to the general surgeon. This is particularly true of the chapters on the surgical diseases and wounds of the nasal cavities and accessory sinuses. Great advances have been made during the past few years in the diagnosis and treatment of infections of the sinuses accessory to the nasal cavities, and the editors did well in allowing so much space to these important subjects.

The genitourinary surgeon likewise will find the subjects pertaining to his department very well presented. The publishers have maintained the same good standard of work as shown in the previous volumes.

A Text-Book of Surgery. By George Emerson Brewer, A.M., M.D., Professor of Clinical Surgery at the College of Physicians and Surgeons, Columbia University, New York. Second Edition. Cloth. Pp. 875, with 415 engravings and 14 plates in colors and monochrome. Price, $5. Philadelphia: Lea & Febiger, 1909.

Judging from the increased size of this book over the previous one, the author agreed with his critics that for a practical working text-book in surgery the brevity of the former edition was not commendable. In it the effort to condense was carried too far. Many important subjects were treated too briefly, and others were omitted. This fault has been remedied in the present edition. For instance, whereas only twenty lines were given to the subject of gangrene in the first edition, four pages are now devoted to it. Seven pages have been added to the chapter on tumors. The treatment of empyema is discussed far more fully than before. The same is true of many other subjects, so that the work can now be recommended as a really excellent text-book in surgery, standing midway between the brief manuals and the more voluminous treatises. No attempt is made to discuss fully all improved methods of surgical treatment, but they are mentioned; one method, the one most in vogue, is given the preference in description. In one particular the book is open to criticism: when a drug is mentioned in connection with treatment, the dose is not given. In some instances this is a serious oversight. For example, in the treatment of aneurisms by means of the injection of gelatin, it is merely stated that the subcutaneous injection of a 1 per cent. solution of gelatin in normal salt solution is useful. Nothing is said as to the dose or as to whether the treatment is to be repeated. The chapter on anesthesia is brief but good. The chapters on surgical pathology are excellent, and the chapter on shock cannot fail to prove useful to both student and practitioner.

Atlas of External Diseases of the Eye. By. Dr. Richard Greeff, Professor of Ophthalmology in the University of Berlin and Chief of the Royal Ophthalmic Clinic in the Charité Hospital. Only Authorized English Translation by P. W. Shedd, M.D., New York. Half leather, with 54 plates and 84 figures in color. Pp. 135. Price, $10. New York: Rebman Co.

This is an almost literal translation from the text of Greeff's "Atlas der äusseren Augenkrankheit," and contains prints from the original plates illustrating that well-known work. While a careful comparison of the two atlases is not to the advantage of the American edition, either in type or paper, yet practitioners interested in external diseases of the ocular apparatus, but not familiar with German, will find in the English edition of Professor Greeff's works a most valuable aid in the diagnosis of those affections.

The German color-printer has faithfully portrayed the soft, almost indescribable, appearances of the diseased tissues—so difficult to present by any of the color schemes at our disposal. In this connection too much cannot be said commendatory of the remarkable fidelity with which the author, the sculptor (Herr Kolbow) and the optical firms (Mueller of Wiesbaden and Höning of Berlin) who supplied the artificial eyes for the models, and the printers have caught and fixed the pathologic alterations in such difficult subjects as eye patients. These illustrations, from the Berlin Pathoplastic Institute, are the best of their kind that have come to our notice.

By these means almost every ordinary and most of the rare diseases affecting the eyelids, the conjunctiva, the sclera, cornea, iris and lacrimal apparatus are portrayed, while many concurrent lesions on the face and head chiefly of dermatologic interest, are pictured.

A System of Medicine. By Many Writers. Edited by Sir Clifford Allbutt, K. C. B., M.A., M.D., LL.D., D.Sc., F.R.C.P., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge, and Humphrey Davy Rolleston, M.A., M.D., F.R.C.P., Senior Physician, St. George's Hospital. Vol. VI. Diseases of the Heart and Blood-Vessels. Cloth. Pp. 844, with illustrations. Price, $1.50 net. New York: The Macmillan Co., 1909.

This volume is devoted entirely to a discussion of the diseases of the heart and blood-vessels. It contains nearly 850 pages, and the discussion of the subjects contained therein is full and complete. The first chapter, which is especially well worth reading, is devoted to a consideration of the physics of the circulation by Sherrington. It is a fitting introductory to the study of valvular lesions. Osler contributes a new article on Stokes-Adams disease. M'Crae has revised the original article by Dreschfeld on acute simple endocarditis. William H. Welch contributes the articles on thrombosis and embolism. There is little to criticize and much to commend in a work of this kind because it is complete. By no means the least of the valuable features of this book is the list of references appended to each article, although it is unfortunate that American medicine is mentioned so seldom.

The Practitioner's Visiting List for 1910. Flexible leather. Wallet-shaped, with flap, pocket, calendar for two years and valuable data. Price, $1.25. Philadelphia: Lea & Febiger.

This visiting list is especially adapted to the wants of the general practitioner; it is well bound, compact, and contains matter well selected to give the puzzled doctor the hint that he needs. Doses and therapeutic reminders are given of which the physician should ordinarily be independent, but which he may occasionally find useful.

Medicolegal

Principles of Constitutional Law Governing Health Regulations —Board Enjoined from Sending Elderly Woman with Anesthetic Leprosy to Pesthouse—Personal Liability of Members of Health Board

The Supreme Court of South Carolina says, in the case of Mary V. Kirk vs. Wyman and others, constituting the Board of Health of the City of Aiken (65 S. E. R. 387), that the principles of constitutional law governing health regulations by statute and municipal ordinance may be thus stated:

First. Statutes and ordinances requiring the removal or destruction of property or the isolation of infected persons, when necessary for the protection of the public health, do not violate the constitutional guaranty of the right of enjoyment of liberty and property, because neither the right to liberty nor the right of property extends to the use of liberty or property to the injury of others.

Second. The creation by legislative authority of boards of health, with the discretion lodged in them of summary inquiry and action, is a reasonable exercise of the police power and the rules and resolutions within the scope of the authority of such boards have the force of legislative enactment. Legislative power lodged by the Constitution exclusively in the General Assembly is not delegated to such boards, but they are merely the agency for carrying out the legislative enactment.

Third. Arbitrary power over persons and property could not be conferred on a board of health, and no attempt is made in the Constitution or statutes to confer such power. On the contrary, it is implied in all such legislation that the board shall exercise the police power conferred in view of the constitutional guaranty that no person shall be deprived of life, liberty or property without due process of law, or be denied the equal protection of the laws. It is always implied that the power conferred to interfere with these personal rights is limited by public necessity. From this it follows that boards of health may not deprive any person of his property or his liberty, unless the deprivation is made to appear, by due inquiry, to be reasonably necessary to the public health; and such inquiry must include notice to the person whose property or liberty is involved, and the opportunity to him to be heard, unless the emergency appears to be so great that such notice and hearing could be had only at the peril of the public safety.

Fourth. To the end that personal liberty and property may be protected against invasion not essential to the public health—not required by public necessity—the regulations and proceedings of boards of health are subject to judicial review, by an action for damages or for injunction or other appropriate proceeding, according to the circumstances. In passing on such regulations and proceedings, the courts consider, first, whether interference with personal liberty or property was reasonably necessary to the public health, and second, if the means used and the extent of interference were reasonably necessary for accomplishment of the purpose to be attained.

Fifth. In exercising the jurisdiction to review the regulations and actions of such boards by injunction or other proceeding, the courts cannot invade the province of the legislative branch of the government. Inasmuch as it is the province of the legislative branch to determine what laws and regulations are necessary to the public health, statutes and regulations made, and measures taken under such statutes, and intended and adopted to that end, are not subject to judicial review; but the courts must determine whether there is any real relation between the preservation of the public health and the legislative enactment, or the regulations and proceedings of boards of health under authority of the statute. If the statute or the regulations made or the proceedings taken under it are not reasonably appropriate to the end in view, the necessity for curtailment of individual liberty, which is essential to the validity of such statutes and regulations and proceedings, is wanting, and the courts must declare them invalid, as violative of constitutional right.

Sixth. In all judicial inquiry, with respect to health laws and regulations, every intendment is to be allowed in favor of the validity of the statute and the lawfulness of the measures taken under it.

In this case it was admitted that Miss Kirk, who was not only a lady of refinement, highly esteemed in the community, but who was quite advanced in years, was afflicted with anesthetic leprosy contracted while engaged in missionary work in Brazil. The evidence furnished of the opinions of both specialists and general practitioners of medicine was quite full, and led to the conclusion that there was hardly any danger of contagion from Miss Kirk, except by touch, or at least close personal association. What was more important than these opinions was the uncontroverted fact that she had for many years lived in the city of Aiken, attended church services, taught in the Sunday school, mingled freely with the people in social life, resting on the opinion of a distinguished London specialist that her disease was not contagious, and in all that time there had been nothing to indicate that she had imparted the disease to any other person.

But while there was a strong showing that the anesthetic form of the disease was only slightly contagious, the court considers that when the distressing nature of the malady was regarded, it was manifest that the board was well within its duty in requiring the victim of it to be isolated. However, it does not think that there was any necessity to send such a patient to the pesthouse, which in this instance was a structure of four small rooms in a row, with no piazzas, used previously for the isolation of negroes with smallpox, situated within a hundred yards of the place where the trash of the city, except its offensive offal, was collected and burned. Nothing but necessity would justify the board of health in requiring even temporary isolation in such a place for an elderly lady, enfeebled by disease, and accustomed to the comforts of life, and the court thinks there was a strong prima facie showing that there was no good reason to conclude that such necessity existed.

For these reasons the court affirms a decree granting a temporary injunction restraining the board of health from removing Miss Kirk to the city hospital for infectious diseases, or pesthouse, the order containing the condition that it was not to be understood as interfering with the board of health in maintaining such quarantine regulations as they might deem necessary for the public safety. Still the court wishes it understood that it cannot too strongly emphasize the caution which courts should exercise in entertaining applications for injunction against boards of health.

The court agrees, it says, with the circuit judge, also, on the point that an action for damages against the members of the board of health as individuals would not afford Miss Kirk an adequate remedy. In some jurisdictions it has been held that the members of a board of health incur personal liability for a mistake in destroying property on the ground that it is dangerous, when in fact it is not. But in South Carolina it must be held, on the authority of White vs. City of Charleston, 2 Hill, 576, that the members of a board of health are not personally liable for errors in their official conduct, when they exercise their honest judgment. Personal liability depends on proof of bad faith. True, bad faith may be shown by evidence that the official action was so arbitrary and unreasonable that it could not have been taken in good faith. But if there were such showing, the remedy by action for damages would not be adequate where the health or life of the citizen is by force unnecessarily imperiled. Protection from the loss of health or life is the only adequate relief in such a case.

"Partial" Versus "General" Insanity as a Defense to Crime

The Supreme Court of Kansas holds, in the homicide case of State vs. Moore (102 Pac. R. 475), that, if the trial court see fit, it may recognize monomania, or so-called "partial insanity," as distinguished from "general insanity," when instructing the jury in a criminal case involving that form of mental derangement as a defense; but it is not imperative that it should do so, and, if the proper tests of criminal responsibility for the act in question be stated in the instructions, the substantial rights of the defendant are sufficiently protected.

To destroy criminality, monomania, or so-called "partial," as distinguished from "general insanity," must dethrone the reason and judgment to the extent the law requires with reference to the act which is the subject of prosecution. The verdict must always be determined by the quality of that act. That act is the product of "insanity," as the law defines that term, or not. The person committing it is either sane or insane for all purposes of the verdict and judgment.

It is true that the law recognizes every form of insanity or delusion which renders an accused mentally incapable of knowing the nature and quality of the act done, and that it was wrong; but it is also true that the law recognizes no form of insanity, although the mental faculties may be disordered or deranged, which will furnish one immunity from punishment for an act declared by law to be criminal, so long as the person committing the act had the capacity to know what he was doing and the power to know that his act was wrong.

Therefore the form or species of insanity with which it is claimed a defendant was affected is not, in the last analysis, material, and need not be discriminated in the instructions; and, if the proper test of criminal responsibility for the act in question be given, the substantial rights of the defendant have been protected. In some cases it might be helpful, and in others it might be confusing, to the jury, for the court to open up the subject of the various forms in which mental derangement may be manifested. The refusal to do so can scarcely ever be erroneous, if otherwise full and proper instructions be given.

1. **Functions of Muscle Cells of Cardiovascular System.**—Bishop says that cardiac muscle cells have retained some of the properties of nerve fibers. They have five sorts of properties, stimulus production, excitability, conductivity, contractility and tonicity. If supplied with appropriate nutriment the heart-muscle cells possess a power to secrete internally a material capable of causing contraction. This is stored up, and is exhausted by the beat. A specialization of function is necessary for the coordination of the heart action. Rest and proper nourishment are essential factors in heart treatment. The classification of arteriosclerosis is founded on the tonicity of the median coat. Hypertrophy of the media is the principal factor in many cases of atheroma and arteriosclerosis. Hypertonicity leads to sclerosis and hypertrophy of the media, and atheroma is apt to be engrafted on the diseased artery.

6. Abstracted in THE JOURNAL, July 17, 1909, p. 226.

8. **Variations in Posterior Horn of Lateral Ventricle.**—Out of 64 adult brains, not specially chosen, examined by Curran, all

grades of variation were encountered, from the dilated ventricle of hydrocephalus internus to complete occlusions of the posterior horns, and these were numerous. In a large percentage of brains the tip of the posterior horn of the lateral ventricle is cut off from communication with the rest of the ventricle by a constriction and adhesions about the calcar avis. In many cases the adhesion of the walls is complete throughout the occipital lobe, making the so-called short horn. The ependyma, however, remains on the two adherent walls and can always be seen in this position, proving that this part at one time during development was occupied by the cavity which has since become obliterated. In many cases the tip of the posterior horn has a very narrow communication with the rest of the lateral ventricle, and, on account of the thinness of the wall about the calcar avis, any change in pressure is likely to close this aqueduct and produce a temporary disturbance in the circulation of cerebrospinal fluid, and might give rise to pain or other symptoms. Any of the above conditions would obstruct the circulation of cerebrospinal fluid. When the posterior horn is entirely or partially closed by adhesion of the walls, any increase of internal pressure would tend to break the adhesions and reestablish the normal posterior horn. Might not such straining on the adhesions, asks Curran, *give rise to pain or other symptoms?*

That the calcarine fissure and the cerebellum, which modify so much the shape of the posterior horn, are developing rapidly about the time of the appearance of convulsions in infants is an interesting coincidence. The large proportion of anomalies in the posterior horns of brains from institutions is significant. In all cases the ventricle should extend far into the occipital lobe, and traces of its having been there at one time during development are always to be found. The relationship of the optic radiation and other structures to the posterior horn are important facts for consideration in connection with the causes of temporary scotoma and migraine, and possibly other conditions. The condition of the posterior horn should be examined in all cases of obscure cerebral diseases or mental disorders.

10. **Cesarean Section.**—In general, the results in this series of 100 cases were as follows: Eight patients died, a mortality of 8 per cent. There were 43 primary operations in the series. One mother died, and one baby was lost. The cause of the maternal death was general peritonitis, probably due to some slip in the operative technic. One child died a few minutes after delivery after breathing well; the cause of death was congenital heart disease. One patient ran a moderate febrile temperature for the first few weeks after operation, but recovered without pelvic or other symptoms. In other words, among the primary operations there was one maternal and one fetal death, 2.3 per cent., and one patient who had an abnormal convalescence. Twenty-six cases were included in the secondary class. One mother died, on the eighth day following operation, of pyemia. At the time of operation it was known that she was a poor risk, as she was suffering from chronic nephritis, but the condition which demanded operation was an extreme degree of vaginal atresia following an old laceration, so that abdominal delivery was imperative. Two children died following delivery. One small, poorly developed child, the mother being a rachitic dwarf, died four hours after delivery, and the other died on the seventeenth day following delivery, of inanition.

The complications following operation were distinctly more marked in the secondary cases than in the primary. Three women suffered from phlebitis of one or both legs. One patient ran a febrile convalescence, but eventually recovered completely. In 3 cases the abdominal wound broke down and the convalescence was necessarily prolonged. In the secondary cases, then, we find a maternal mortality of approximately 4 per cent., and a fetal mortality of 8 per cent., while the complications which appeared during the convalescence were much more prominent than in the primary operation. In the late cases there were 31 operations. Among these there were 6 maternal deaths, approximately 19 per cent. The cause of death in all cases except one was general peritonitis. Five babies were lost, either being dead before operation was begun or dying shortly after delivery. Of the 6 mothers who died, 3 had been in labor twenty-four hours or more. In one, high forceps had been tried and failed. One patient was suffering from acute nephritis as a complication, and in one a sponge was left in the abdomen at the time of operation.

21 *A New Artificial Leech. A. M. MacWhinnie, Seattle, Wash.

14. **Treatment of Hay Fever.**—In about 80 cases which Scheppegrell has observed, ragweed was the causal factor in every case except one, which was undoubtedly due to the goldenrod. The pollen of the ragweed is not simply a mechanical irritant, like dust, as is usually supposed, but it contains a pungent aromatic compound which acts as an irritant on the nasal mucosa. As a scientific basis for the prevention of hay fever, one must either cause the entire disappearance of the plant which produces the causative factor of the disease, or must artificially develop in patients susceptible to it that degree of tolerance which naturally exists in persons not suffering from hay fever. The former is neither possible nor practicable. The alternative, therefore, is the development of an artificial tolerance to the irritating pollen in persons subject to hay fever. Such a tolerance is gradually developed in the progress of the disease.

As the staminate flowers of the ragweed contain its pollen, these are made use of by Scheppegrell. At a period of time varying from two to six weeks the pollen of the staminate flowers are inhaled by the patient. These inhalations are at first made two or three times a day, and later, as the time of the usual development of the disease approaches, more frequently. The inhalation is followed by a slight attack of sneezing, some lachrymation, and a watery discharge from the nose, and then a congestion of the mucous membrane of the nostril. As no inflammation exists, these effects are not disagreeable or painful, and ordinarily pass off in the course of an hour. If the patient takes a walk or other form of exercise immediately after the application is made, the congestion of the mucous membrane is less marked. In a few days, the applications produce less reaction, and more pollen may be inhaled and the inhalations made a greater number of times. Gradually the reactions become less and finally are not observed by the patient. When this is the case the patient is immune to an attack of hay fever at this time.

This immunity, Scheppegrell finds, is not permanent, and therefore the treatment should not be discontinued until the regular advent of the hay-fever season, when it should be entirely discontinued, as the natural pollen of the air takes the place of the artificial inhalations. Scheppegrell believes that if the staminate inhalations are resumed after the cessation of the hay-fever period, a permanent tolerance will gradually be developed which will give the patient permanent immunity.

17. **Amebic Enteritis.**—The case reported by Gage was one of amebic dysentery of about two years' standing, and could not be considered a very promising one for treatment. The results show, however, that in some chronic cases the patients can be permanently cured by medical treatment, and they also illustrate the value of the ipecac treatment. The cure in this case is permanent, as shown by the freedom from symptoms in four years and the results of examinations of the stools. The character of the stools shows some intestinal indigestion, which may be the result of the former dysentery. The uncinariasis was very mild. There were only eight worms in the intestine, there was no distinct anemia, the eosinophilia was not marked, and there were no symptoms of the disease. The thymol treatment was successful in getting rid of all the worms. The trichomonads were evidently not greatly affected

by the thymol. They were present in the stools afterward, but apparently not as numerous. They were not present in the stools after the ipecac was given. The trichocephalus eggs were found on only one occasion and then only four. No worms were seen in the stools.

21. **New Artificial Leech.**—MacWhinnie uses a sterile artificial leech made of glass, which is so shaped as to show the exact amount of blood being extracted, and can be used at any particular point that is desired. It has three openings, the larger being for abstraction on the temple, while the smaller one on the same plane is made for attachment either with a large rubber bulb, or direct connection with a Pynchon pump. The large end has a diameter of 1¼ inches, and is adapted for the temple, cheek, or, in fact, any part of the face. The two small openings are arranged for the tragus, while the larger one may be used for the mastoid as well. When the surfaces are irregular the small opening is desired. Being of glass it can be sterilized, and its size is convenient. At the lower end of the bulb a cork is inserted which is removed when the proper amount of blood is obtained, and the whole instrument is then sterilized. No guess is needed as to whether the blood is being withdrawn or not, or in what amount. The artificial leech is first applied for several minutes to create a congestion, which will raise the part from 2 to 5 millimeters. Several small punctures are then made, preferably with a cataract knife. The artificial leech is then applied as described.

38 *Phagocytic Immunity in Streptococcus Infections. J. C. Meakins, New York.
39 *Character of Protein Metabolism in Chronic Nephritis. P. A. Levene, L. Kristeller and D. Manson.

33. **Specific Hemolysin of Human Erythrocytes.**—Disease appears to change the resistance of red cells to specific hemolysin only in special cases. Of 41 cases of secondary anemia, 1 only showed a decrease. In 2 of 3 cases of pernicious anemia and in 2 cases of leucemia resistance was decreased also, and a decrease occurs sometimes in obstructive jaundice. An increase in resistance was seen in 2 cases of hemophilia and in 1 of chronic parenchymatous nephritis and in 1 of congenital icterus (Minkowski). The resistance of human corpuscles to hypotonic salt solution and to specific hemolysin are entirely independent of each other and the resistance to salt solution is much the more variable.

35. **Influence of Thyroidectomy on Alimentary Glycosuria.**—Removal of the thyroid glands causes a rise in the assimilation limit for dextrose, and if the parathyroids are left this result is permanent. The thyroids probably inhibit normally the direct combustion of the sugar in the muscles.

36. **Differentiation of Trypanosome Species.**—The experiments show that the guinea-pig is an unfavorable animal in which to preserve trypanosomes if the therapeutic immunity reaction is to be employed in the differentiation of trypanosome species, because trypanosomes of common origin which had not come in contact with medicaments of any sort behave like different species after having been passed through guinea-pigs for twelve months.

37. **Test for Circulating Antibodies in Cancer.**—The growth of adenocarcinoma in white rats was unaffected when the tumor animal was joined experimentally (parabiosis) with a resistant animal,

38. **Streptococcus Infections.**—In certain streptococcus infections, such as acute endocarditis and tonsillitis, there may be considerable increase in the opsonin for the streptococcus causing the infection and little or no increase for streptococci from other sources. Hence it is argued that but little benefit may be expected from the inoculation with bacteria killed by heat unless with streptococci causing the infection.

39. **Protein Metabolism in Chronic Nephritis.**—Results indicate that it may be important for dietetic-therapeutic purposes to establish the eliminating efficiency of the kidneys for nitrogenous substances.

44. **Exercise and Adolescent Heart Development.**—Foster claims that vigorous exercise is necessary for the boy at puberty to secure the normal heart development. During the training of athletics and in contests allowance should be made for the fact that the lesser muscular development of the prepubescent heart makes it unfit for prolonged violent exercise. Hearts of all school boys should be examined and suitable regulation of exercise suggested when necessary. No boys with heart murmurs should be allowed to indulge in the physical training work involving decidedly increased heart action or to enter any athletic contests.

54 *Partial Responsibility of the Insane. F. T. Simpson, Hartford, Conn.
55 *Hemolysis in Diagnosis of Malignant Neoplasms. H. S. Arnold, New Haven.

49. **Medical Aspect of Gastric Insufficiency.**—Stoll has found the following regimen to be satisfactory in these cases: Massage along the course of the colon before rising each morning; a glass of cold water before dressing; eat liberally of vegetables and fruits, especially stewed prunes and figs; drink two glasses of water between meals, and most important of all, have a regular time for going to stool whether the inclination is

present or not. The crouching position, as when a chamber is used, is sometimes of advantage, and colonic massage at that time is very efficacious. The food should be of a kind which leaves considerable residue in the intestine. Sour milk, buttermilk or cider may be drunk between meals and at bedtime. Agar-agar in amounts of from one-half to one ounce daily is effectual. Bran in place of breakfast food may be used, and a small amount of olive oil taken at meal times will very often be all that is required to insure a daily stool. Olive-oil injections given just before retiring are the most satisfactory means of obtaining a cure in very chronic cases; given at first every night; later, every other night, and so gradually make the interval longer until they are no longer required. With very weak abdominal muscles, exercises and electricity *are indicated.*

52. **Dermatitis Following Local Application of Cow's Milk.**—The rash in Steele's case occurred with perfect regularity, coming out about fifteen minutes after the milk touched the skin, lasting at first an hour, then gradually existing a shorter and shorter time until after twenty-one days it ceased to appear. In appearance it was a bright red blush, not raised, at times sharply circumscribed, at others with fading pink edges to normal skin. In extent it conformed quite closely to the area touched by the milk, either by running over the chin or cheek from the mouth or on the area to which milk was purposely applied. At no time did it resemble urticaria or cause apparent itching. With the exception of being a deeper red, it exactly imitated areas of skin often noted in babies where, for instance, the inner aspects of the knees have been pressed together for some considerable time during sleep, which on separation show a transient blush, lasting perhaps longer than the same condition in adults and being more brilliant in color.

69. **Differentiation of Diphtheria Bacillus.**—As the result of much experimental work, Fisher concludes that the diphtheria bacillus cannot be identified accurately by its morphology and its cultural characters alone. True diphtheria bacilli always ferment dextrin within forty-eight hours and never saccharose. This reaction, however, is not distinctive of the virulent bacillus diphtheria, since it is also given by certain non-pathogenic organisms, having the same morphology. Out of 13 unselected races which fermented dextrin, 5 were totally avirulent. Since bacilli which fail to ferment dextrin are much more commonly encountered, the fermentation test would, in the majority of cases, be conclusive. Practically, it is of little value on account of the necessity of obtaining the bacilli in absolutely pure culture. Animal inoculation is, at present, therefore, the only reliable practicable method of identifying the diphtheria bacillus. To exclude the virulent diphtheroids, a guinea-pig immunized with diphtheria antitoxin must be inoculated also.

84 *Pathology and Bacteriology of Plague in Squirrels. G. W. McCoy, U. S. P. H. and M.-H. S.
85 *Resistance of Human Erythrocytes to Cobra Venom. R. Weil, New York.

76. **Fecal Bacteria of Healthy Men.**—The number of fecal bacteria that grow on artificial media is only a small fraction of the bacteria microscopically visible in feces. In addition to the colon bacillus group, sporogenic aerobic bacilli and sporogenic anaerobic bacilli are normally present in human feces. *B. welchii* is normally present in the feces. It is to be noted, however, that the total number of sporogenic bacilli is much greater than indicated by the cultures, and there are a number of bacterial species in normal feces not yet cultivated.

77. **Bacillus Diphtheriæ in Throat Cultures.**—Granular forms of diphtheria bacillus in throat cultures appear to be increasing in frequency in Cleveland, whereas the barred forms have almost disappeared. The presence of these granular forms renders the distinction between genuine diphtheria bacillus and a granular non-pathogenic bacillus more difficult.

79. **Anhydrous Sodium Sulphite in Endo's Medium.**—Wherry was unable to arrest the progress of inoculation leprosy in a white rat by means of injections of rat lepra bacilli killed by heat. Injections of killed bacilli some days previous to the injection of living bacilli resulted in marked delay in the progress of the disease.

Leprosy tissue from a rat on being ground up with powdered glass and extracted with salt solution and then shaken up with commercial chloroform, the chloroform then being evaporated, gives a residue containing millions of bacilli free from all cellular elements and other bacteria. The method might be of assistance in detecting lepra bacilli in human cases.

82. **Effect of Salts on Normal Opsonins.**—The maximum opsonification occurs at the normal (alkaline) reaction of the serum, and any change of this reaction in either direction diminishes the opsonic effect. This result of altered reaction is due in large measure to its effect on the thermolabile element of the opsonin. Magnesium chlorid appears to stimulate phagocytic action of leucocytes.

83. **Subacute Plague in Man.**—The first case of undoubted squirrel plague in man which has come to autopsy in America is reported. The lesions were similar to those of subacute plague in guinea-pigs, rats and squirrels. The authors have not seen any lesions like those observed in this case—lobular pneumonia and multiple abscesses of the lymph nodes, lungs, liver and kidneys—in any other case of human plague.

84. **Plague in Squirrels.**—The commonest lesion of plague in the ground squirrel is a bubo and this may be the only one. There may be also purulent foci in the spleen, the liver, the lung and the kidney. Smears from purulent material fail to show pest bacilli in the majority of cases. The diagnosis was made by inoculation.

85. **Resistance of Human Erythrocytes.**—Weil has tested the resistance of human red corpuscles to a number of hemolytic agents, and of these agents cobra venom has given results of special interest. The condition which presents the most marked degree of resistance is syphilis after it has passed the

primary stage. Normal individuals and various diseased conditions give variable resistance within certain narrow limits, but this does not approach the degree of resistance characteristic of syphilis. The practical application of the reaction remains to be worked out. Theoretically, it is interesting because it illustrates a definite alteration in cells in response to an infection.

93 *The Parasitism of Psoriasis. J. F. Schamberg, Philadelphia.
94 *Idiopathic Multiple Hemorrhagic Sarcoma (Kaposi): Trauma an Etiologic Factor (?). D. Lieberthal, Chicago.

92. **Etiology of Psoriasis.**—According to Pollitzer, rheumatism, gout, neurosis and heredity are not direct etiologic factors in the production of psoriasis, but in the present state of our knowledge it can neither be denied nor affirmed that they may have some bearing on the obscure conditions of the system which render it more or less susceptible to this especial infection. Psoriasis is one member of a group of parakeratoses to which seborrhea corpis, and, in part, eczema seborrhœicum, belong, and is most probably due to an external microbic infectious agent.

93. **Parasitism of P[illegible]** [illegible]ys that it might be argued that the [illegible] psoriasis in the vast majority of subjects,operates against the assumption that psoriasis is a local parasitic disease due to an exogenous organism. It might, furthermore, be argued that if the lesions of psoriasis are due to the implantation of a parasite on the skin of a susceptible individual, inoculation with lymph, blood and scales from a diseased patch on the healthy skin in the same patient might be reasonably expected to reproduce psoriasis lesions. Lack of knowledge, however, concerning possible conditions of immunity in this connection, makes it unwarranted to deduce any positive conclusions of the character indicated. The inability to autoinoculate psoriasis patients would not at all affect the hypothesis that psoriasis is a constitutional, infectious disease. From what has been stated, it is obvious that no definite conclusion as to the parasitism of psoriasis is warranted. The mode of growth and configuration of the patches, the occasional instances of apparent communication of the disease, and the Destot inoculation are arguments in favor of parasitism which cannot be decisively brushed aside. On the other hand, the general behavior of the disease, the common experience of observers as to absence of contagion and the almost uniform failure of inoculation experiments constitute strong evidence against parasitism.

94. **Multiple Hemorrhagic Sarcoma.**—This is the fourth case of this disease reported by Lieberthal. The three previous cases were reported in THE JOURNAL, Dec. 6, 1902, and Oct. 10, 1908.

9 Severe Eclampsia in Early Pregnancy: Recovery. A. S. Campbell.

2. **Laceration of Cervix Uteri.**—Colyer states that when the first stage of labor is normal, the presenting part descends into a dilated cervix by which it is not tightly grasped, and hence no lacerations are likely to ensue. But should it so happen that the membranes rupture before the end of the first stage, then the presenting part will descend into an incompletely dilated cervix by which it will be lightly grasped. In the latter case, second-stage pains will ensue, and the uterus will transmit a force to the presenting part, which will stretch the cervix at a rate in excess of its physiologic yielding power, and, as a rule, beyond its momentarily elastic limit, and thus lead to its laceration. The nearer the os approaches to full dilatation the greater will be the force exerted on it by the presenting part, because not only does the angle between the two become increasingly acute, but the pains will be stronger. It is not uncommon when the membranes rupture late to find that the presenting part is driven through an incompletely dilated cervix in one or two pains, thus proving how rapidly the stretching may take place. In those cases in which the membranes rupture early, we should not find lacerations of the cervix so common, for in them, as a rule, labor is slow until the cervix is sufficiently dilated to allow the presenting part to enter, and when it does enter the pains gradually change in character from those of the first stage to those of the second. In the second stage contraction and retraction of the longitudinal fibers become marked, and thus tend to draw up the cervix and lead to a more rapid dilatation of the os. But even with these compensations a slight rupture appears to occur in most cases.

4. **Blood-Tight Uterus and Involution.**—Physiologically, Longridge says, involution of the uterus may be considered as an acute autolytic degradation of the muscular tissue. It takes place in two stages, a rapid and a slow stage. The rapid stage differs from the slow, in that in the former the uterus is practically anemic and the reaction of the tissue is acid, whereas in the slow stage the reaction is alkaline and the blood is slowly percolating through the vessel walls. The transition from one stage to another is marked by an increased excretion of nitrogen.

8. **Intestinal Drainage.**—The method employed by Mamourian consists in utilizing the Murphy button with a piece of soft rubber tubing (about a yard or more long) as follows: A purse-string suture of silk is passed round one of the ends of the rubber tube, the male or female half of the button is introduced into the lumen and the thread tightened so as to grip the neck of the button. Next, a segment of the distended bowel is clamped and a linear purse-string suture inserted. The gut is incised, the other half of the button placed in position, and finally the two sections of the instrument united in the usual way. The anastomosis between bowel and rubber tube is complete, and on removing the clamp there is no leakage, and the fecal contents pass out of the tube into a jar containing some kind of deodorant well away from the area of operation. The purse string on the bowel need only be secured by a temporary knot so that the suture may be tightened and the incision instantaneously closed after the withdrawal of the button, the bowel being reclamped before the button is removed. If one opening does not give satisfactory drainage, the process can be repeated with as many coils as the surgeon desires, or a piece of drainage tubing can be passed up the soft tube through the button into the bowel and the intestines "milked" without the hands coming into contact with fecal matter.

This method is, perhaps, more serviceable in cases which require immediate colotomy. The Murphy button, this author considers, is superior to Paul's tubes, as its use involves no danger of detachment or leakage. The soft tube, with half the button in position being ready, the operation can be completed in a few minutes. The button, as a rule, remains *in situ*, affording good drainage for at least four days, during which time there is no necessity even to inspect the wound. When the button comes away the peritoneal cavity is completely shut off and the wound partially healed. The artificial anus thus made leaves nothing to be desired.

16 Acute Torsion of the Splenic Pedicle, Recovery after Splenectomy: Case of Floating Liver Cured by Operation. P. Patterson.

11. **Myotonia Atrophica.**—The leading features of this disease are summarized by Batten as follows: A patient, usually a male, between the twentieth and thirtieth year of life, begins to complain of weakness of the limbs and wasting of muscles. Some stiffness of muscles may also be complained of. On examination he is found to have weakness, and atrophy of the facial muscles, of the sternomastoids, of the flexors and extensors of the wrist, of the extensors of the leg or dorsiflexors of the foot, and the striking myotonic phenomenon that after grasping an object he has difficulty in relaxing his grasp. Pathologically, there is a general cirrhotic condition of the muscles, such as is found in muscular dystrophy. The spinal cord may show some degeneration in the posterior column, but the other portions of the nervous system are normal.

13. **Streptococcal Infection in Diphtheria.**—Mathieson records observations made in 80 consecutive cases of diphtheria admitted to the Infectious Disease Hospital, Leith. A bacteriologic examination of the throat of each patient was made on admission and at intervals during the stay in hospital, and the clinical progress was recorded. In 9 out of 80 cases a marked streptococcal infection of the throat was found at one time or other in the course of the disease. Out of these 9, 5 developed symptoms corresponding to those described by Sevester and Martin about the thirteenth day. In the remaining 71 patients in whom no streptococcal infection of the throat was at any time found, 2 showed epiphenomena about the thirteenth day. In other words: (a) 55 per cent. of the streptococcal cases developed "thirteenth-day" symptoms; and (b) 2.8 per cent. of the non-streptococcal cases developed these symptoms.

The following is a brief summary of the 7 cases in which "thirteenth-day" phenomena were observed: (a) Streptococcal cases: (1) punctate erythema + albuminuria; (2) sore throat + joint pains + rise in temperature (100.8 F.); (3) otorrhea; (4) punctate erythema; and (5) punctate erythema + rise of temperature (99.4 F.); (b) Non-streptococcal cases: (1) erythema multiforme; and (2) punctate erythema + rise of temperature (99.8 F.).

19 *How to Deal with the Quack Medicine Traffic. J. C. McWalter.
20 The Relation of Health to Industry. B. A. Whitelegge.

19. **Quack Medicine Traffic.**—According to McWalter, the solution of the quack medicine problem is simply this—that makers of the nostrums should be required to set forth the ingredients on the label. He says: This is practically the American remedy, but, after all, the problem in the United States has been very much like the problem with us; the results appear to be satisfactory, and we should not be too proud to follow a good example from a kindred people. Assuming that the disclosure of the ingredients is the remedy for the quack medicine trouble, how can we insist on it? An act of Parliament at once suggests itself, and would be the procedure if we had a minister of public health; but we have no such minister, and the difficulty of procuring such a bill might be insuperable. All the power and influence of our association has not been able to bring the new medical act into being, and if we cannot suppress open unqualified practice of medicine by law, we can scarcely hope to interfere with an insidious form of the evil which brings the treasury in 340,000 pounds a year. The indications for the treatment of the quack-medicine trouble are, then, to get statutory powers to insist that the ingredients be set forth on the label—and pending legislation to that effect to have the various medical officers of health to deal with the makers under the food and drugs act, with the help of the analytical records of the British Medical Association. The association might well help the campaign by other means—namely, by furnishing chemists with printed results of the analysis of the nostrums on which most of the public money is being spent at the moment. These should be sent out under the authority of the association, otherwise they would surely be questioned by the quacks. In addition to chemists, this might also be distributed to all doctors in the country, whether members of the association or not, as well as to the public analysts, sanitary authorities and the clergy.

36 Modern Assistancy. A. Sheperd.

23. **Treatment of Inoperable Sarcoma.**—Up to the present time Coley has had 52 cases of inoperable sarcoma successfully treated with the mixed toxins of erysipelas and *bacillus prodigiosus*. Of these, 35 patients have remained well from 3¼ to 16 years; 28 from 5 to 16 years; and 14 from 10 to 16 years.

26. **Rheumatic Heart Disease in Children.**—When a child is attacked by rheumatism, no matter in what form, it is comparatively exceptional for the heart to escape, while the whole brunt of the disease may fall on that organ, other evidences of rheumatism being either absent or so slight as to pass unnoticed. In other words, the heart is in early life the most vulnerable part of the body to the rheumatic poison. Moreover, when the joints escape, it by no means follows that the cardiac affection is likely to be slight; in fact, the reverse is often the case, and the poison seems to spend itself on the heart. In many of the most severe and intractable examples of rheumatic carditis which Carr has seen, joint affection has been conspicuous by its absence.

Another possible reason why the serious character of rheumatism in childhood is not sufficiently appreciated is, perhaps, because the cardiac lesion often seems at first so insignificant. Valvular disease in a child is a much more serious thing than in an adult because it interferes so materially with the nutrition of the growing tissues. Hence it is one of the wasting diseases of childhood, and when at all severe leads to marked stunting of growth, anemia and actual wasting; the rapid development at puberty imposes an especial strain on such children. The danger is greatest in cases of mitral obstruction, because the orifice becomes surrounded by a ring or curtain of fibrous tissue, which tends slowly to contract, like newly formed fibrous tissue in any other part of the body. Thus the orifice, instead of enlarging proportionately to the increased quantity of blood which has to pass through it as the body grows, may slowly become smaller, and to this extent, therefore, the lesion is progressive, although, as a rule, endocarditis due to rheumatism differs from that due to degeneration in tending to remain stationary when once the secondary results of the inflammation are complete. In children, when once the heart has been damaged, relapsing, subacute attacks of endocarditis and pericarditis and also of myocarditis, are prone to occur, often in the most insidious fashion and quite independently of any obvious joint inflammation. Consequently they are very liable to be overlooked and are a common cause of irreparable damage to the heart.

The following are the evidences on which Carr chiefly relies in forming an opinion in these cases: 1. The presence of subcutaneous rheumatic nodules; (2) any pyrexia, especially in the evening; (3) joint pains; (4) any sudden development of, or increase in, anemia; (5) excessive and persistent rapidity of the pulse. The first and most essential point on which to insist in the treatment of such a case is the paramount importance of prolonged and complete rest. The child must not merely be kept in bed, but must remain absolutely recumbent for a period depending on the severity of the attack, but for not less than several weeks. During this time, the child should be kept on very light diet, for his bodily needs are reduced to a minimum, and it is desirable to avoid anything calculated to raise the arterial tension, and so throw additional strain on the left ventricle. Constipation is often very troublesome and most undesirable, so that laxatives must be given frely, as required. Great caution must be exercised in allowing the child increased freedom of movement, as very little exertion or excitement will markedly quicken the pulse and may even lead to a sharp rise in temperature. Sodium salicylate or aspirin, heart stimulants and the ice bag over the precordium are employed as occasion arises.

29. **Intermittent Claudication.**—Greig reports a case due to a venous, not an arterial, affection, which was followed by recovery.

45 *Hernia of the Ureter. (L'uretérocèle.) P. Caccia.
46 *End-Results of Operative Treatment of Mammary Cancer. (Résultats éloignés de l'ablation du sein pour cancer.) Fidelin.
47 *Operative Inoculations of Cancer. (Les inoculations opératoires du cancer.) F. Jacoulet.

45. **Ureterocele.**—Caccia warns that this rare condition should be suspected when a cord is found in a hernial sac. The diagnosis is made most readily in femoral hernia when access is obtained through the inguinal canal. He reports 2 cases and reviews the 22 which he has found on record and also 4 others in which an extraperitoneal cystocele was combined with the hernia of the ureter. A lipoma seems to be a frequent factor in dragging the ureter down in this way.

46. **History after Removal of Mammary Cancer.**—Fidelin's article is based on the experiences in five important French surgical clinics, the ultimate outcome being known in 234 cases of cancer of the breast, which he compares with others' statistics. A final cure is rare; recurrences are known twenty and thirty years after the operation without symptoms in the interim. An important lesson from his investigations is the benefit that may be derived from several successive operations in certain cases with multiple local recurrences. Life is prolonged, and the patient's courage maintained. The proportion of recurrences has dropped from 76 per cent. in 1865 to 25 per cent. by 1905 in certain large statistics, but the best technic to prevent recurrence is still undecided. Fidelin thinks that Handley's suggestions that the cancer spreads as a vine grows and that the technic should be based on this principle, certainly deserve attention.

47. **Inoculation of Cancer During its Removal.**—Jacoulet is convinced that study of operative inoculation will explain many cases of recurrence of cancer. The soil seems to be especially favorable for the development of cancer germs in certain patients. He has known of two unreported cases and reviews three others in which cancer of the tongue recurred from inoculation of cancer cells, by the instrument in some of the cases. The site, the size and the shape of the recurring nodule and the absence of recurrence in the scar, all point to inoculation by a solution of continuity in the mucosa, the result of application of the forceps to draw the tongue out, the recurring nodule developing at the point where the tongue was seized while the primary growth on the base of the tongue or roof of the mouth was being excised. In another case, the bistoury with which a cancerous gland had been cut out was used to make a vertical incision to liberate the lip drawn up too much by the suture after removal of an epithelioma on the lower lip. Several months later the patient returned with a recurring nodule at the point where the bistoury had been used first. The symmetrical incision was free from recurrence as the bistoury had been wiped free from contamination by the first incision.

49 *Experimental Research on Functional Mitral Insufficiency. C. Lian.

49. **Experimental Mitral Insufficiency.**—Lian's research on dogs has confirmed the fact that dilatation of the left ventricle may entail functional mitral insufficiency revealed by a systolic souffle at the apex. It may subside and reappear, with the heart apparently normal in the intervals. The condition most liable to entail it is when extreme dilatation is accompanied by factors inducing simultaneous overexertion of the left heart and fatigue of the myocardium.

50 *Acceleration of Gaseous Interchanges and Organic Demineralization in the Pretuberculous and Tuberculous Condition. (L'accélération des échanges respiratoires et la déminéralisation organique chez les prétuberculeux et chez les phtisiques.) A. Robin.
51 Production of Heat by Living Beings and Influence of Food. [illegible] ar les êtres vivants et la [illegible] re.) Weiss.
52 [illegible] surrénale.) E. Boinet.

50. **Early Differentiation of Tuberculosis.**—Robin's statements in regard to the increased intensity of the nutritional processes in the tuberculous are contrary to the generally accepted ideas as to the necessity for stimulating the biochemical processes in the tuberculous. He insists that treatment should be directed to retard instead of stimulating them, and presents here new arguments to sustain his position, among them a table showing the average consumption of oxygen and production of carbon dioxid in 24 healthy and 44 tuberculous individuals: 3.446 and 3.789 c.c. of oxygen being consumed in the healthy and 5.16 and 4.714 in the tuberculous, and 2.620 and 2.931 carbon dioxid produced in the healthy, and 3.785 and 3.569 in the 35 tuberculous men and 19 tuberculous women per kilogram of weight and per minute. The difference is still more striking in the tables that are computed per minute irrespective of the body weight. The difference grows constantly greater as the tuberculosis progresses, and this acceleration of the respiratory interchanges is frequently observed in the offspring of the tuberculous and also in alcoholism, in extreme fatigue from any cause, in worry and in all the predisposed. The "predisposition" to tuberculosis is thus seen to be a nutritional anomaly identical in all the predisposed and capable of being recognized and measured. Robin's further research has also confirmed the fact that the proportion between the inorganic residue of the urine and the total residue (in normal conditions 30 to 32 per cent.) is unusually large just preceding and during the first and second stages of tuberculosis, dropping below normal in the terminal stage. The bones of tuberculous individuals show abnormally small proportions of phosphoric acid, lime

and silica. The consumptive seems to drain the bones of the mineral elements to eliminate them in excessive proportions, while the tissues need these very elements to sustain them in their struggle against the tubercle bacillus. The points for diagnosis of the predisposition or early infection and for prognosis are thus: (1) increased production of carbon dioxid and consumption of oxygen; (2) organic demineralization; (3) reduction in the "coefficient of robustness" (estimated by Pignet by subtracting from the height the sum of the chest measure and weight. For example: height 1.69 meters, minus the chest measure 0.73 meters, plus the weight 82 kilograms, gives 14 as the *coefficient de robusticité.*); (4) abnormally rapid growth; (5) unusual thinness in proportion to the food ingested; (6) early fatigue; (7) long, narrow and shallow chest, small xiphoid angle, the ribs oblique, etc.; (8) exaggeration of the cutaneous radiation of heat; (9) sensation of internal heat, the average temperature generally above the average, and rapid rises of temperature; (10) abnormally small difference between the temperature in the axilla and the temperature of the skin elsewhere; (11) abnormally rapid rate of respiration and pulse; and (12) abnormally low arterial pressure. In the neurotic-gouty type, on the other hand, the pulse and respiration rate is abnormally low and the arterial blood pressure high, while the radiation of heat and the average temperature are below normal. It is thus possible, Robin declares, to recognize the pretuberculous and the incipient stages of tuberculosis and by appropriate measures to transform the soil and thus reenforce the natural defensive processes.

52. **Organotherapy of Suprarenal Disease.**—Boinet reports the postmortem findings in 44 cases of various suprarenal affections, all confirming the existence of a sclerous inflammation of the suprarenals in the syndrome of Addison's disease as also with mere bronzing of the skin and mucosæ and with the abnormal pigmentation sometimes observed in the tuberculous. In 20 other cases of sclerosis of the suprarenals, encountered in the course of 900 autopsies of adults at the Hotel Dieu, the diagnosis had been uncertain on account of the absence of pronounced bronzing. Suprarenal insufficiency is suggested by a combination of one or more circulatory disturbances (small unstable pulse, low arterial tension, the "white line" or track of pallor that follows when a blunt instrument is drawn along the abdominal wall, tachycardia and chilliness); digestive disturbances (anorexia, vomiting, diarrhea or constipation); toxic nervous disturbances resulting from irritation of the various nerve plexus around the suprarenal capsules, and general disturbances (anemia, emaciation, considerable and progressive amyotrophy). The diagnosis is confirmed by the benefit from organotherapy; benefit is also liable in cases of inoperable cancer in the suprarenals. He advises ingestion of sheep or calf suprarenal capsules fresh or desiccated in a vacuum, or subcutaneous injection of extract of the whole gland. The diagnosis may be facilitated by hastening the development of bronzing by measures for revulsion. Boinet's first communication on this subject was summarized in these columns Nov. 20, 1909, page 1743.

October 24, No. 43, pp. 689-728

55 Acute and Curable Form of Tic Douloureux of the Face. M. Lannois.

53. **Importance of Sterilizing Infants' Clothing.**—Weill has found that the steam laundry cannot be relied on to render infants' diapers and other clothing absolutely sterile. They are liable to acquire germs even on their passage from the laundry to the infant. From a nurse's apron, fresh from a steam laundry in the building, streptococci, staphylococci, diplococci and other germs were cultivated, as also diplococci and bacilli from an infant's cap, laundered and kept two days in the ward linen closet. Weill now insists on having the infants' clothing sterilized by steam under pressure for twenty minutes, the clothing sorted out into sets after laundering, placed in bags and sterilized and kept in the bags until used. One bag contains the inner garments, another the slips and caps; a third, a complete outfit for one infant, and a fourth the gauze sponges used in washing the child. These bags are sterilized and not opened till needed. The bag with the complete outfit is hung on the bedstead, to be used in a hurry at need; the other bags are kept in the linen closet. The nurses are trained never to let their hands come in contact with the part of the linen that comes next the infant's skin. The infant is washed with the gauze sponges taken from the bag, dipped in boiled water, and a little sterilized olive oil poured on them. The nurse's hands are scrubbed and dipped in bichlorid solution before she takes anything out of the bag; she then closes the bag or metal box again at once. The diapers are changed as soon as they are wet. When a bed is vacated, the mattress is disinfected and the iron singed with alcohol. When steam disinfection is not practicable, he has the linen moistened well and ironed till dry. On introducing these strict measures, the mortality in his service dropped from 41.87 per cent. in 1901 to 26.7 per cent. in 1903 and it has been declining since, while the number of cases of acquired cutaneous affections has dropped almost to zero. The infants are all in the same ward, but he tries to keep those with skin diseases at one end of the ward, with separate nurses, and all the nurses are trained to wash their hands with a bichlorid solution before feeding or changing the diaper of an infant. Each child has its own rubber blanket, washed in bichlorid solution each morning; this is spread over a pillow and the infant is placed on it for the physician's inspection. But these precautions failed to ward off infection until the linen was systematically sterilized, when all trouble from this source ceased at once. Not only in prophylaxis but in promoting the healing of cutaneous lesions the sterilized linen has had a good effect. The skin of an infant, he declares, is so sensitive and receptive that it should be regarded and treated just like an open wound. It should be kept covered up, dry and aseptic, while it obeys its inherent tendency to spontaneous anatomic and physiologic repair. This article was presented at the recent international medical congress at Budapest.

54. **Immobilization of Lung by Injection of Nitrogen.**—Balvay and Arcelin have applied this method of treatment in several cases of open tuberculosis and have obtained good results. They injected at first 400 c.c. of nitrogen, repeating the injection four days later with 1,000 c.c., reinjecting about the same amount at similar intervals until the lung was completely immobilized. The pleura absorbs daily from 50 to 80 c.c. of the gas. The febrile temperature drops to normal almost at once, and in the afebrile cases there is no longer a rise of temperature on moderate exertion. By renewing the injection before each menstrual period, it proved possible to render it afebrile in patients who had fever usually at this time. The cough was increased at first after the injections, inducing expectoration. Benefit was observed only in the unilateral cases, however; when both lungs were involved the process in the non-compressed lung became rapidly aggravated, but laryngeal complications were no contraindication. Syncope occurred sometimes in patients with unusually small hearts, but never otherwise. One very anemic patient with multiple lesions and abnormally small heart, died in syncope a few days after a single tentative injection of 500 c.c. of the nitrogen. The principal advantage of the treatment is the way in which it drains the lung and favors cicatrization while preventing secondary infection from inhaled germs and congestion liable to entail hemoptysis.

59 Adherence of Molecules and Its Importance in Various Biologic Phenomena. (Étude de l'adhésion moléculaire et de son intervention dans divers phénomènes biologiques.) M. Mayer.

56. **Treatment of Nephritis with Serum from the Renal Vein.**—Spillmann reviews the evidence that has been accumulating in the last few years in regard to the efficacy of treatment of nephritis with the internal secretion of the kidney as obtained from the blood issuing out of the organ, in the renal vein. He here reports in addition careful research on a number of patients under this treatment, recording day by day the metabolic findings, etc. Goat serum was used, taken from the renal vein, and from 10 to 50 c.c. was the usual dose. The action of the treatment seems to be about the same as that of ordinary organotherapy and the indications are the same for each, that is, conditions suggesting insufficiency of the kidneys. The effect is prompter and more pronounced the milder the kidney affection. The specific effect is seen instructively when the serum is injected into healthy persons, the amount of urine and proportion of chlorids eliminated increasing notably under its influence. His cases included 4 patients with acute and 6 with chronic nephritis, uremic coma or nephritis from corrosive sublimate poisoning in 1 case each, and 2 patients with an intercurrent kidney lesion during pneumonia. Under the influence of the injections the diuresis increased to 6, 8 and even 10 liters during the twenty-four hours; the edema and dyspnea subsided and the heart was markedly relieved. The effect was evidently the result of a specific stimulating action on the kidneys, far more effectual than ordinary diuretics, and effective in many cases in which no benefit was apparent from the latter.

Semaine Médicale, Paris

November 10, XXIX, No. 45, pp. 531-540

60 *Median Suprahyoid Phlegmons. F. Lejars.

60. **Phlegmon Below the Floor of the Mouth.**—Lejars has encountered a number of cases of severe diffuse phlegmon in the floor of the mouth, sometimes pushing up the tongue and sometimes only discoverable by palpation with one finger in the mouth and the other under the chin. At first he treated them by incising in the floor of the mouth but found that this did not reach the root of the evil, while a median incision under the chin, above the hyoid bone, answered the desired purpose most effectually, incising from the tip of the chin nearly to the hyoid bone. He does not wait for pus to collect, the rapid swelling and its extension testifying to the gravity of the infection. The greatest danger is from half measures and delay, and he cites one case in a vigorous man of 65. The swelling was not very pronounced and there was little pain and fever. As the general condition continued good nothing was done for several days, and then a little blood was evacuated through an incision through the floor of the mouth; no pus was discovered but some relief followed. The swelling kept up, however, until the entire chin was involved. The actual cautery was applied and a little pus and serous fluid escaped. Considerable relief followed for two days, but then the tumefaction spread on both sides and an incision showed considerable destruction from the infectious phlegmon and the patient soon succumbed. All this would probably have been averted if the focus had been opened from below in time and amply drained. An incision in the mouth is adequate only when the abscess is circumscribed and, protruding into the mouth, is thus easily accessible.

67 Decline in Tuberculosis Mortality. (Weitere Mitteilungen zur Abnahme der Tuberkulosesterblichkeit.) B. Fränkel.
68 Allowing Parturients to Get Up Early. (Frühaufstehen der Wöchnerinnen.) R. Müllerheim.
69 *Serodiagnosis of Syphilis of the Aorta. (Ueber die Wassermann'sche Reaktion bei Aortenerkrankungen und die Bedeutung der provokatorischen Quecksilberbehandlung für die serologische Diagnose der Lues.) K. Donath.

61. **Bleaching Powder in Dermatology.**—Binz reports further success from the method of treating chilblains with chlorinated lime, mixed with 9 parts of paraffin ointment, and he here reviews Ehrenberg's application of this treatment in 15 cases of intractable erysipelas. He advises commencing with a 5 per cent. ointment at first, applying it once a day, gently, to a small part of the focus, then increasing to 10 per cent. if there is no idiosyncrasy. Sodium thiosulphate may be used in a 1 to 1,000 solution to rinse off the chlorin, if required. No by-effects were observed in the 15 erysipelas cases except injury of the linen if the part was not sufficiently protected.

63. **Disturbances of Suprarenal Functioning in Infectious Diseases.**—Lucksch reports experimental research which confirms his assumption that defective or lacking suprarenal functioning is an important factor in infectious diseases. The injurious influence of the infectious toxins on the chromaffin system should be borne in mind, and the advisability of giving adrenalin to combat the diminishing blood-pressure should be considered.

64. **Bronchoscopy in Internal Medicine.**—Ephraim has found bronchoscopy useful in 95 cases in revealing the cause for the puzzling phenomena observed. In some cases a varix in the trachea explained hemoptysis and permitted a cure. In one case a syphilitic tumor was discovered as the cause of a peculiar cough and the patient was promptly cured. Killian once found and removed a sarcoma in the lower third of the trachea which had caused no symptoms except recurring hemoptysis. Anesthesia is not required for bronchoscopy unless possibly in children.

65. Address at the recent International Medical Congress at Budapest.

69. **Mercurial Test in Serodiagnosis of Syphilis.**—Donath reports a positive serodiagnosis in 85.3 per cent. of 27 cases of pure aortic insufficiency, mesaortitis, or aneurism. Among the 27 cases were 3 in which there was a history of articular rheumatism, but the features of the joint affection showed that it must have been of syphilitic nature rather than true rheumatic polyarthritis. The gummatous form of syphilitic synovitis and ostitis may be accompanied with disturbances suggesting rheumatism. The aortic affection in these cases had previously been regarded as the consequence of infectious articular rheumatism, and in 4 other cases abuse of tobacco and in 2 abuse of alcohol suggested the toxic form of mesaortitis until the serodiagnosis gave the clue. In many patients suspected of syphilis but giving a negative reaction, it is possible to transform the negative into a positive response by a tentative brief course of mercury. He calls this the "provocatory mercurial treatment." After inunction of 12 gm. of gray ointment during the week the Wassermann reaction became positive. This is similar to what is observed in chronic malaria when small doses of quinin may induce an acute phase of the disease.

77 Tuberculosis in Infants. (Zur Klinik der Säuglingstuberkulose.) K. Mallinckrodt.
78 *Correction of Stiff Hip Joint. (Zur Mobilisierung ankylosierter Hüftgelenke.) O. Meyer.

70. **Intraspinal Tumors.**—Oppenheim has been able to cure 13 out of 25 patients with tumors in the spinal canal, thus restoring 52 per cent. to comparative health, including 40 per cent. in which the cure may be called complete. From helpless paralytic cripples they have been restored to active life; one young woman has married since. In 6 of these more favorable cases, the tumor was in the dorsal, in 4 in the cervical, and in 1 in the lumbar region, and in 2 in the cauda equina. He operates even when he is unable to determine the exact location of the tumor within a few segments; as by intradural probing above or below it is possible to disclose the tumor. When the location is very uncertain, it may be wise to wait until the anesthesia has reached a constant upper level, the patient being kept under constant supervision. If the diagnosis wavers between a tumor, circumscribed spinal serous meningitis and hypertrophic pachymeningitis, laminectomy is indicated for all if antisyphilitic treatment affords no relief. He does not advocate surgical intervention on tumors in the spinal cord itself, although benefit may be derived from laminectomy and slitting the dura to give the growth more room.

71. **Sympathetic Ophthalmia.**—Horstmann advises prompt enucleation in prophylaxis of sympathetic inflammation, as no other measures guarantee against it.

72-73. **Serodiagnosis in Syphilitic Eye Affections.**—Schumacher reports examination of 215 ophthalmologic patients and emphasizes the value of the Wassermann test for differentiation, although a positive reaction is rare with inherited syphilis free from recent acute symptoms. His research shows that tuberculosis may develop in the internal eye on the basis of some anomaly due to inherited syphilis. In some cases general tuberculin treatment should be combined with the ordinary antisyphilitic measures. The latter alone suffice when the tuberculous process is latent, but when the syphilis is latent and the tuberculosis manifest, both should be treated to increase the resisting power of the organism and thus render conditions unfavorable for the progress of the tuberculosis.

74. **Tumor of the Frontal Sinus.**—Herzenberg's patient was a man of 56 with a cystic tumor for fifteen years, for which he refused operation until it measured 38 by 35 cm. An incision released 1,800 gm. of a reddish brownish fluid and the brain was found much compressed, while the bone had been worn away. The case is remarkable from the absence of brain symptoms and of pain or other sensation except the discomfort from the large tumor, although after its removal there was room for the fist between the skull and the brain.

78. **Mobilization of Ankylosed Joints.**—Meyer expatiates on the fine results to be attained by excision of part of the joint and interposition of a flap consisting of fat tissue and a thin layer of muscle, fastened with silk sutures to form a cushion between the two bones. He gives a detailed account of a case of ankylosis of the hip joint in which application of this technic restored a cripple to active life. The patient was a woman of 38, with kyphosis from spondylitis in childhood; the coxitis entailing the ankylosis had healed about the age of 14.

90 Fitness for Military Service of German Recruits. (Zur Frage der Militärtauglichkeit der zum einjährigfreiwilligen Dienst berechtigten Wehrpflichtigen Deutschlands.) Schwiening.

79. **Experiments on the Growing Eye.**—Wessely has been examining the influence of various operations on the eye before it has reached its full development. The results show that by transferring experimental research from adult to very young animals a new field is thrown open for investigation in various lines, not only for the eye but for other organs. The growing organ reveals the action of external influences much more instructively than the mature.

85. **Primary Pyelitis.**—Saathoff reports 2 cases of pyelitis with a special Gram-negative bacillus responsible for the process. The special feature of the cases was the involvement of the adjacent tissues in the infectious process; in one patient the infiltration spread through the entire upper left abdomen, in the other the inflammation spread to the veins in the thigh and leg. Notwithstanding this extensive spread of the process, the virulence did not seem to be very great; the general condition persisted remarkably good and there was no loss in weight during the four weeks of fever until the venous thrombosis developed. Suspicion of tuberculosis of the kidney proved unfounded.

87. **Tuberculin Vaselin for the Ocular Test.**—Wolff-Eisner now uses a 1 or 2 per cent. tuberculin vaselin for the ocular test, and states that the mixture keeps perfectly for months, while it is fully as convenient as a solution for the ocular test.

97 Circumcision. E. Schlechtendahl.

91. **Treatment of Obesity by Withdrawal of Meat.**—Albu has found a strict vegetable diet extremely useful in obesity. He believes that it is the easiest, safest and most effectual means of correcting the tendency to undue corpulence without impairing the general health. The aim is to satisfy without giving many calories, and beverages are allowed unrestricted. He gives tables of the calorific value of vegetables with menus for the various seasons. Vegetarians never present the picture of full cheeks and rounded outlines, the difference being mainly in lesser deposits of fat, just what is needed in treatment of obesity. Albu keeps the patient on a strict vegetable diet for from 4 to 6 weeks, then allows from 150 to 200 gm. of lean boiled meat 3 times a week or once a day. This diet is kept up for months without trouble, and protects those inclined to obesity from returning corpulence. If the weight begins to increase he drops the meat again for 4 or 6 weeks. He generally supplements the dietetic regulations by exercises and hydriatic procedures, but these alone are insufficient. He gives the records of several cases in which the weight dropped nearly 40 pounds in the course of a few months by this dieting alone. Fatty heart and digestive disturbances are the main contraindications.

92. **Serum Sickness.**—Ohnacker noted that 21 out of 40 diphtheria patients showed signs of serum sickness, all being injected with No. 178 antitoxin. Tests of this antitoxin showed a peculiar tendency to induce a reaction beyond that of other numbers, the tests showing exanthem in 74 per cent., while it occurred in only 4 per cent. with antitoxin of another date. The antitoxin was tested by injecting 0.1 c.c. into the skin by the Schleich infiltration technic. Besides the 100 cases thus treated, a number of control tests were made on other persons with salt solution and human serum, with and without a preservative. In another series the antitoxin No. 178 was injected into the left arm and antitoxin of another date into the right; a reaction was observed in 77 per cent. on the left and in only 5 per cent. on the right arm. He concludes from all this research that the serum sickness is due to some prop-

erty of the serum used and not to any property on the part of the one injected, although some patients are naturally a little more sensitive than others.

93. **Combined Electric Method of Treating Cancer.**—Müller reports a case which has attracted attention, as the tumor on the back of the head had been examined by a number of physicians in Berlin, the general verdict being inoperable sarcoma. The tumor was as large as a child's head, and the glands in the neck were swollen. The cachexia and loss of 41 pounds in a few months, and inefficacy of potassium iodid confirmed the assumption of malignant disease, but the extension from the vertex to the neck and over the parietal region forbade the thought of an operation. Roentgen treatment was energetically applied, combined with application of high-frequency electric currents of high tension. Müller has been successful with this combined method in a number of small superficial tumors and in this case the tumor retrogressed after the third sitting so that the skin lay in folds, and by the tenth the entire tumor had vanished, nothing being left after the twelfth sitting but a minute nodule behind one ear. The glands in the neck had subsided to normal size by the eighth sitting. He used water-cooled tubes so that there was no sign of an *x*-ray burn. The scalp was rubbed with alcohol and greased during the treatment, but this was the only medication. The hat band of 65 cm. is now reduced to 58 cm., and the patient has gained 24 pounds in weight. Klemperer confirms Müller's statements, having had the patient in his charge and having informed the family of the fatal prognosis. The greater was his astonishment when the patient returned four months later in robust health and no trace of the tumor. No microscopic examination was made. In this preliminary communication Müller gives no more than the above description of his technic.

98. This is a translation of an article published in *Northwest Medicine*, August, 1909.

99. **Stenosis of the Pylorus and Roentgen-Ray Examination.**—Jonas writes from the Roentgen laboratory of the general hospital at Vienna to call attention to the importance of the discovery of antiperistalsis as a sign of incipient stenosis. It is readily distinguished with Roentgen examination and the bismuth taken for the purpose supplies the best conditions for determining the peristalsis if the patient has eaten a roll or its equivalent before taking the bismuth. The antiperistalsis is the radiologic equivalent of the impending but not yet developed "rigidity of the stomach" (*Magensteifung*). This first stage of pyloric obstruction consists merely in moderate distention of the caudal part and antiperistalsis, but there is as yet no atony of the fundus, no profuse vomiting nor colic. As compensation fails, vomiting occurs and the fundus shows atony, while in the ultimate stage the caudal part is extremely dilated, with other signs of stagnation.

102. **Thermopenetration.**—Considerable interest has been aroused by this method of inducing heat in the depths of the tissues by the local resistance to the passage of high-frequency currents. Bernd has applied the measure 2,000 times, but warns that the technic requires practice on the cadaver and on animals before it can be safely applied to man. He uses it in gonorrheal, rheumatic and other affections in which local application of heat promises good results. Tuberculous affections do not seem to be influenced, and it does not seem to be able to destroy the gonococci in the urethra but is proving useful in the complications of gonorrhea in the male.

103. **The Opsonic Index During Tuberculin Treatment.**—Kössler and Neumann tabulate the findings in 18 cases which seem to show that the opsonic index is of comparatively little moment as a guide in tuberculin treatment.

104. **Non-Gonococcus Ophthalmia in the New-Born.**—Lindner reports from Fuchs' eye clinic that he has been able to infect monkeys with the secretions from ophthalmia neonatorum, free from gonococci but containing cell inclusions, such as Prowazek has described as trachoma bodies. The course of the transmitted affection resembled in every respect that of transmitted trachoma. Consequently, he asserts that in these cases of ophthalmia neonatorum, the trouble is evidently a form of trachoma affecting the conjunctiva of the new-born, no matter whether the granules of the inclusions are to be regarded as a specific product of the reaction to the causal agent or as the causal agent itself.

120 *Possibility of Immunization against Syphilis by other Venereal Affection. (Sulla eventuale immunizzazione della sifilide.) B. Calabrese.

113. **Neuroses of the Sympathetic System in Measles.**—Licciardi discusses a recent epidemic of measles at Catania which involved young and old; in one family two men of 40 and 47, with a baby had the disease, and several instances were known in which the disease had occurred for the third time. Bronchitis and pneumonia were frequent and severe complications, as also gastrointestinal catarrh, sometimes presenting a syndrome suggesting typhoid and accompanied by signs of meningeal irritation. In several cases he encountered a neurosis of the sympathetic system as he describes in detail in 3 typical instances. One was in a child, nearly 2 years old; during the eruptive stage of measles spasm of the larynx developed. The vocal cords seemed to contract slowly to close the throat completely until the carbon dioxid accumulating in the blood stimulated the respiration center and induced a profound inspiration. The spasm was then suspended for an instant. While considering intubation, mustard to the chest, and bromids, cannabis indica and belladonna were given and in the

70. Intraspinal Tumors.—Oppenheim has been able to cure 13 out of 25 patients with tumors in the spinal canal, thus restoring 52 per cent. to comparative health, including 40 per cent. in which the cure may be called complete. From helpless paralytic cripples they have been restored to active life; one young woman has married since. In 6 of these more favorable cases, the tumor was in the dorsal, in 4 in the cervical, and in 1 in the lumbar region, and in 2 in the cauda equina. He operates even when he is unable to determine the exact location of the tumor within a few segments, as by intradural probing above or below it is possible to disclose the tumor. When the location is very uncertain, it may be wise to wait until the anesthesia has reached a constant upper level, the patient being kept under constant supervision. If the diagnosis wavers between a tumor, circumscribed spinal serous meningitis and hypertrophic pachymeningitis, laminectomy is indicated for all if antisyphilitic treatment affords no relief. He does not advocate surgical intervention on tumors in the spinal cord itself, although benefit may be derived from laminectomy and slitting the dura to give the growth more room.

71. Sympathetic Ophthalmia.—Horstmann advises prompt enucleation in prophylaxis of sympathetic inflammation, as no other measures guarantee against it.

72-73. Serodiagnosis in Syphilitic Eye Affections.—Schumacher reports examination of 215 ophthalmologic patients and emphasizes the value of the Wassermann test for differentiation, although a positive reaction is rare with inherited syphilis free from recent acute symptoms. His research shows that tuberculosis may develop in the internal eye on the basis of some anomaly due to inherited syphilis. In some cases general tuberculin treatment should be combined with the ordinary antisyphilitic measures. The latter alone suffice when the tuberculous process is latent, but when the syphilis is latent and the tuberculosis manifest, both should be treated to increase the resisting power of the organism and thus render conditions unfavorable for the progress of the tuberculosis.

74. Tumor of the Frontal Sinus.—Herzenberg's patient was a man of 56 with a cystic tumor for fifteen years, for which he refused operation until it measured 38 by 35 cm. An incision released 1,800 gm. of a reddish brownish fluid and the brain was found much compressed, while the bone had been worn away. The case is remarkable from the absence of brain symptoms and of pain or other sensation except the discomfort from the large tumor, although after its removal there was room for the fist between the skull and the brain.

78. 79. Experiments on the Growing Eye.—Wessely has been examining the influence of various operations on the eye before it has reached its full development. The results show that by transferring experimental research from adult to very young animals a new field is thrown open for investigation in various lines, not only for the eye but for other organs. The growing organ reveals the action of external influences much more instructively than the mature.

85. Primary Pyelitis.—Saathoff reports 2 cases of pyelitis with a special Gram-negative bacillus responsible for the process. The special feature of the cases was the involvement of the adjacent tissues in the infectious process; in one patient the infiltration spread through the entire upper left abdomen, in the other the inflammation spread to the veins in the thigh and leg. Notwithstanding this extensive spread of the process, the virulence did not seem to be very great; the general condition persisted remarkably good and there was no loss in weight during the four weeks of fever until the venous thrombosis developed. Suspicion of tuberculosis of the kidney proved unfounded.

87. Tuberculin Vaselin for the Ocular Test.—Wolff-Eisner now uses a 1 or 2 per cent. tuberculin vaselin for the ocular test, and states that the mixture keeps perfectly for months, while it is fully as convenient as a solution for the ocular test.

91. Treatment of Obesity by Withdrawal of Meat.—Albu has found a strict vegetable diet extremely useful in obesity. He believes that it is the easiest, safest and most effectual means of correcting the tendency to undue corpulence without impairing the general health. The aim is to satisfy without giving many calories, and beverages are allowed unrestricted. He gives tables of the calorific value of vegetables with menus for the various seasons. Vegetarians never present the picture of full cheeks and rounded outlines, the difference being mainly in lesser deposits of fat, just what is needed in treatment of obesity. Albu keeps the patient on a strict vegetable diet for from 4 to 6 weeks, then allows from 150 to 200 gm. of lean boiled meat 3 times a week or once a day. This diet is kept up for months without trouble, and protects those inclined to obesity from returning corpulence. If the weight begins to increase he drops the meat again for 4 or 6 weeks. He generally supplements the dietetic regulations by exercises and hydriatic procedures, but these alone are insufficient. He gives the records of several cases in which the weight dropped nearly 40 pounds in the course of a few months by this dieting alone. Fatty heart and digestive disturbances are the main contraindications.

92. Serum Sickness.—Ohnacker noted that 21 out of 40 diphtheria patients showed signs of serum sickness, all being injected with No. 178 antitoxin. Tests of this antitoxin showed a peculiar tendency to induce a reaction beyond that of other numbers, the tests showing exanthem in 74 per cent., while it occurred in only 4 per cent. with antitoxin of another date. The antitoxin was tested by injecting 0.1 c.c. into the skin by the Schleich infiltration technic. Besides the 100 cases thus treated, a number of control tests were made on other persons with salt solution and human serum, with and without a preservative. In another series the antitoxin No. 178 was injected into the left arm and antitoxin of another date into the right; a reaction was observed in 77 per cent. on the left and in only 5 per cent. on the right arm. He concludes from all this research that the serum sickness is due to some property of the serum used and not to any property on the part of the one injected, although some patients are naturally a little more sensitive than others.

93. **Combined Electric Method of Treating Cancer.**—Müller reports a case which has attracted attention, as the tumor on the back of the head had been examined by a number of physicians in Berlin, the general verdict being inoperable sarcoma. The tumor was as large as a child's head, and the glands in the neck were swollen. The cachexia and loss of 41 pounds in a few months, and inefficacy of potassium iodid confirmed the assumption of malignant disease, but the extension from the vertex to the neck and over the parietal region forbade the thought of an operation. Roentgen treatment was energetically applied, combined with application of high-frequency electric currents of high tension. Müller has been successful with this combined method in a number of small superficial tumors and in this case the tumor retrogressed after the third sitting so that the skin lay in folds, and by the tenth the entire tumor had vanished, nothing being left after the twelfth sitting but a minute nodule behind one ear. The glands in the neck had subsided to normal size by the eighth sitting. He used water-cooled tubes so that there was no sign of an *x*-ray burn. The scalp was rubbed with alcohol and greased during the treatment, but this was the only medication. The hat band of 65 cm. is now reduced to 58 cm., and the patient has gained 24 pounds in weight. Klemperer confirms Müller's statements, having had the patient in his charge and having informed the family of the fatal prognosis. The greater was his astonishment when the patient returned four months later in robust health and no trace of the tumor. No microscopic examination was made. In this preliminary communication Müller gives no more than the above description of his technic.

98. This is a translation of an article published in *Northwest Medicine*, August, 1909.

99. **Stenosis of the Pylorus and Roentgen-Ray Examination.**—Jonas writes from the Roentgen laboratory of the general hospital at Vienna to call attention to the importance of the discovery of antiperistalsis as a sign of incipient stenosis. It is readily distinguished with Roentgen examination and the bismuth taken for the purpose supplies the best conditions for determining the peristalsis if the patient has eaten a roll or its equivalent before taking the bismuth. The antiperistalsis is the radiologic equivalent of the impending but not yet developed "rigidity of the stomach" (*Magensteifung*). This first stage of pyloric obstruction consists merely in moderate distention of the caudal part and antiperistalsis, but there is as yet no atony of the fundus, no profuse vomiting nor colic. As compensation fails, vomiting occurs and the fundus shows atony, while in the ultimate stage the caudal part is extremely dilated, with other signs of stagnation.

102. Thermopenetration.—Considerable interest has been aroused by this method of inducing heat in the depths of the tissues by the local resistance to the passage of high-frequency currents. Bernd has applied the measure 2,000 times, but warns that the technic requires practice on the cadaver and on animals before it can be safely applied to man. He uses it in gonorrheal, rheumatic and other affections in which local application of heat promises good results. Tuberculous affections do not seem to be influenced, and it does not seem to be able to destroy the gonococci in the urethra but is proving useful in the complications of gonorrhea in the male.

103. **The Opsonic Index During Tuberculin Treatment.**—Kössler and Neumann tabulate the findings in 18 cases which seem to show that the opsonic index is of comparatively little moment as a guide in tuberculin treatment.

104. **Non-Gonococcus Ophthalmia in the New-Born.**—Lindner reports from Fuchs' eye clinic that he has been able to infect monkeys with the secretions from ophthalmia neonatorum, free from gonococci but containing cell inclusions, such as Prowazek has described as trachoma bodies. The course of the transmitted affection resembled in every respect that of transmitted trachoma. Consequently, he asserts that in these cases of ophthalmia neonatorum, the trouble is evidently a form of trachoma affecting the conjunctiva of the new-born, no matter whether the granules of the inclusions are to be regarded as a specific product of the reaction to the causal agent or as the causal agent itself.

120 *Possibility of Immunization against Syphilis by other Venereal Affection. (Sulla eventuale immunizzazione della sifilide.) B. Calabrese.

113. **Neuroses of the Sympathetic System in Measles.**—Licciardi discusses a recent epidemic of measles at Catania which involved young and old; in one family two men of 40 and 47, with a baby had the disease, and several instances were known in which the disease had occurred for the third time. Bronchitis and pneumonia were frequent and severe complications, as also gastrointestinal catarrh, sometimes presenting a syndrome suggesting typhoid and accompanied by signs of meningeal irritation. In several cases he encountered a neurosis of the sympathetic system as he describes in detail in 3 typical instances. One was in a child, nearly 2 years old; during the eruptive stage of measles spasm of the larynx developed. The vocal cords seemed to contract slowly to close the throat completely until the carbon dioxid accumulating in the blood stimulated the respiration center and induced a profound inspiration. The spasm was then suspended for an instant. While considering intubation, mustard to the chest, and bromids, cannabis indica and belladonna were given and in the

course of a few hours the spasm subsided. It returned again two days later when it yielded as before to the same measures. Another child had attacks of typical asthma for the first time during measles; nothing of the kind was known in the family before. In a third child the spasm affected the intestines; the intense pain was not accompanied by any objective signs of trouble but continued unmitigated until relieved by the same measures used in the other cases, bromids, cannabis indica and belladonna.

117. Biologic Factors in Pathology of Pregnancy.—Mangiagalli does not regard heart disease as such a serious factor in the pathology of pregnancy as some assume. In his experience the mortality has been only 6.5 per cent. and this only when the food and conditions in general were very unfavorable. The placenta is no longer considered as merely an osmotic and dialyzing membrane interposed between the mother and fetus; it is now known to be an organ with important functions, and biologic factors alone can explain the changes in the kidney with pregnancy. All the organs seem to have their resisting powers in respect to infections reduced during pregnancy, but pneumonia seems to be the most threatening of all. The prognosis is always grave and the effect of artificial interruption of the pregnancy is not felt in time to be of much use in this self-limited disease. This measure, however, he declares, is frequently indicated in case of renal or hepatic complications, but only exceptionally in heart disease.

119. Sign of Intestinal Stricture from Neoplasm.—Minerbi reports a case of tumor palpable to the left of the umbilicus with other phenomena suggesting a tuberculous process involving the intestine and peritoneum except for the absence of ascites, fever and response to the tuberculin test. This threw the balance of the diagnosis in favor of cancer, and this assumption was confirmed by the behavior of the tumor when air was blown into the rectum from a bicycle pump. At each stroke of the piston the palpating hand on the tumor felt a kind of expansive pulsation in the tumor similar to the pulsation in the wall of an aneurism in an artery at each systole. This prompt action of the insufflated air was felt only in one side of the tumor, which confirmed the assumption that the growth was a lymphosarcoma in the retroperitoneal glands which in the course of its three years of growth had involved and finally induced stenosis in the descending colon. The factors indispensable for this air-pump sign of stenosis are continence of the sphincter, stenosis not far above and sufficiently pronounced to confine the air, with the walls of the bowel infiltrated with the growth so as to be palpated while some of the wall still retains sufficient elasticity to yield to the pressure of the insufflated air. The discovery of a second small tumor in the epigastrium suggested the lymphatic nature of the cancer in this case.

120. Immunization Against Syphilis by Other Venereal Disease.—Calabrese states that he has been impressed with the fact that among a thousand individuals with constitutional syphilis examined who had contracted some other venereal disease during the secondary phase of their syphilis, none had been infected with these other affections before except in a very small proportion, not over 7.5 per cent., and in these there had been an interval of several years before the syphilitic infection. He calls attention to this fact in his experience and urges others to collect information on this point, his impression being that individuals infected with gonorrhea or soft chancre are immune to infection with syphilis. The toxins elaborated by the gonococcus and the Ducrey bacillus, while harmless, comparatively speaking, for the bearer, seem, he asserts, to exert an immunizing power against the pale spirochete capable of aborting incipient syphilis entirely. He is now conducting research in this line, striving for eventual immunization against syphilis by this means.

121. Phenol in Tetanus (Baccelli Method).—Conforti remarks that the Baccelli method of treating tetanus is in such general use in Italy and with such constantly good results that no one thinks now of reporting cases any more than instances of recovery from diphtheria under antitoxin treatment. All accept the favorable outcome as a matter of course: the record includes now several hundred cases, with or without associated antitetanus serum. It was his unusual experience to encounter 3 typical cases of traumatic tetanus in the course of one month recently, and he reports them in detail to show the workings of the Baccelli method. [It was described in THE JOURNAL, June 3, 1899, page 1249. The main features are first to cleanse the wound thoroughly with strong antiseptic solution, place the patient in a quiet dark room, plug the ears to keep out unavoidable noises, and give subcutaneous injections of a 2 or 3 per cent. solution of phenol at two or three hour intervals, generally along the spinal column. If the case is of moderate severity, Baccelli commences with 0.2 gm. (3 grains) of the phenol in the 24 hours, rapidly increasing to double or triple this amount. The patient in the grip of tetanus bears astonishingly large amounts of phenol. He claims that it antagonizes the tetanus toxin and quiets the nervous system. In one of his cases 0.72 gm. of phenol was given daily for 6 days, the patient receiving 511 separate injections with lesser amounts in the course of 36 days with final recovery. The text-books mention the Baccelli method, but without much comment, as a rule. Green's Encyclopedia of Medicine, 1908, states that experimental research seems to prove the method valueless, citing Courmont, 1899, von Török, 1900, and Guillaumin, 1902. But French in his "Practice of Medicine," Babes in "Twentieth Century Practice of Medicine," Woods and others have reported encouraging results with the phenol. Woods' article was summarized in THE JOURNAL, Sept. 16, 1899, page 727.—ED.] Conforti supplemented the carbolic injections with the usual sedatives, bromids, chloral or morphin. The incubation had been two weeks in the first 2 cases and the patients, men of 18 and 62, recovered; about 22 gm. of the carbolic acid had been injected in 24 days in the first and 18 gm. in 21 days in the other case. In the third case the patient, a man of 57, succumbed in less than 48 hours after the first symptoms of tetanus after an incubation of one week. The youngest patient exhibited a tendency to hallucinations and mild delirium after subsidence of the convulsions, without fever. Zeri has reported a similar case of a mild, transient psychosis following the tetanus in a patient treated by this method, but Conforti knows of other cases in which the tetanus toxin alone could be incriminated: no carbolic acid had been used.

PUS TUBES IN THE MALE

SURGICAL AND VACCINE TREATMENT *

WILLIAM T. BELFIELD, M.D.
CHICAGO

The pus infections of the urinary duct have been for centuries the object of clinical study and surgical exploration; those of the less conspicuous seminal duct remained virtually unexplored until the twentieth century. Pus tubes in the male are to-day as generally unrecognized and surgically ignored as were the pus tubes of the female thirty years ago. Even the accessible epididymis has constantly harbored gonorrheal pus, until recently undetected and undisturbed by surgery.

CLINICAL ANATOMY

Four anatomical features of the seminal duct are clinically important:

1. Ampulla and vesicle are closed by a sphincter of smooth muscle. This muscle, generally ignored by clinicians and anatomists alike, was first described by Kölliker,[1] was named by Hyrtl[2] the "adductor" of the seminal vesicles, and is figured by Bardeleben and Haeckel[3] as the "interampullary muscle." Careful dissection, however, reveals it as a true "compressor ductium seminalium," whose contraction closes the orifices of ampullæ and vesicles. The existence of this sphincter explains the clinically important fact that liquids injected into the vas enter and distend the vesicle before they escape through the ejaculatory duct. This was first demonstrated on the cadaver by de Graaf, and on the living subject by myself.

2. The distensibility of the seminal duct beyond the epididymis is slight; for vesicle and ampulla are enclosed in an unyielding envelope, and the vas has a thick covering of circular muscle fibers. When, therefore, the minute natural outlet, the ejaculatory duct, is occluded by inflammatory swelling or otherwise (and this often happens) the seminal bladder does not expand indefinitely as does the urinary bladder. When the accumulating pus exceeds the limited capacity of ampulla and vesicle, their contractions force the excess contents through the only other outlet, the vas. Since the vas is powerfully contractile, the epididymis far less so, the tail of the epididymis becomes the catch-basin for pus from the vesicle—not only in gonorrhea, but in other urethral infections. This is the pathology of epididymitis, and of the so-called reflex peristalsis of the vas.

Pus infection of the vesicle plus occlusion of the ejaculatory duct, therefore, soon converts the entire seminal duct into a closed abscess. Hence an opening into the vas (vasostomy) affords relief of tension and exit for pus from the entire duct, vesicle and epididymis included, as well as a means of medicating vas and vesicle by injections.

3. Ampulla and vesicle are closely bound to the base of the bladder; infections of the former may, therefore, induce bladder contractions. Cases of "irritable bladder" and "chronic cystitis" without discoverable cause in the urinary tract are thus explained; and these may be promptly relieved by draining the seminal duct, though treatment directed to the bladder be futile. For example, a man 68 years old, referred for prostatectomy to relieve cystitis, was found to have merely a pus infection of left vesicle and epididymis. The vas was opened and pus escaped; the interval between urinations, previously less than an hour, at once lengthened to four hours.

Seminal retention without infection may also induce "irritable bladder." In one such case a distended vesicle was discovered and emptied by the finger in the rectum, a mass of inspissated mucus and spermatozoa being expressed into the urethra; the symptoms of bladder irritation immediately ceased. Doubtless the relief of such irritation, often secured through massage of the prostate (and vesicles), is thus induced.

In "prostatism without prostatic enlargement," the partial retention of urine is at times due to adhesions between the base of the bladder and the adjacent seminal duct.

The symptoms of "cystitis" may, then, proceed from lesions of the seminal as well as of the urinary channel; clinically these two ducts are Siamese twins.[4]

4. Ureter, vesicle and vas are in intimate relation in what I long ago demonstrated to be the "broad ligament of the male."[5] This is a sac of the rectovesical *fascia* which covers vesicles, ampullæ, ejaculatory ducts and utricle, and which is in the new-born male—as in the adult female—a fold of peritoneum; in early *childhood* the serous covering recedes to the top of the vesicles. My designation of seminal duct suppurations as "pus tubes in the male," criticized in certain quarters, is then anatomically well founded.[6]

At the upper angle of the masculine broad ligament on each side, the ureter is crossed by the vas *deferens* and is separated from the top of the seminal vesicle only by fascia. Adhesions following infections of vas and vesicle may, therefore, bind and obstruct the adjacent ureter. Morgan[7] found exactly this condition on exploratory operation, and cured the patient by liberating the ureter from its adhesion to the vesicle; and Young[8] later reported a similar case in which adhesions to the vesicle had produced occlusion of the ureter and destruction of the kidney, compelling nephrectomy.

[1] Kölliker: Gewebelehre des Menschen, iii, 466.

[2] Hyrtl: Lehrbuch der Anatomie, ii, 80.

[3] Bardeleben and Haeckel: Atlas of Applied Anatomy, Fig. 158.

[4] The production of bladder symptoms by lesions of the seminal vesicle has been emphasized by Fuller also (Post-Graduate, January, 1906).

[5] Park: Treatise on Surgery, 1896, ii, 494.

[6] The homology of this fascia with the broad ligament of the female is proved by the embryological studies of Cunéo and Veau (Journal de l'Anatomie et de la Physiologie, 1899, p. 235), who state that "the seminal ducts, thus included between two peritoneal culs-de-sac, are contained in a transverse fold, a *veritable masculine broad ligament*."

As Tandler and Zuckerkandl note, the ureter dilatation incident to prostatic hypertrophy occurs above the point where the ureter is crossed by the vas deferens, and is obviously due to pressure by the latter; hence division of both vasa should be a part of surgical attempts to relieve the results of such hypertrophy, when renal retention exists.

This intimate relation between the juxtavesical ureter and the seminal duct seems, therefore, responsible for considerable kidney and ureter disease hitherto unexplored.

Renal pain—"lumbago" or "nephralgia"—often occurs when the vesicle is distended, and is promptly relieved by emptying the vesicle either through massage or vasostomy. Apparently simple distention of the vesicle may compress the ureter and thus distend the renal pelvis.

IMPOTENCE AND STERILITY

The juxtaposition of the seminal ducts to bladder and rectum renders the relation of pus tubes to vesical and rectal tenesmus sufficiently obvious. The abdominal pain from an infected vas simulates that of ureteral calculus and of appendicitis, and in at least one instance led to a mistaken diagnosis and futile operation for appendicitis by a competent surgeon. The "neurasthenia" caused by prostatovesiculitis, commonly explained by an obscure nervous influence, seems rather a toxemia from the local infection; for it is often relieved by evacuation of pus from the genital tract.

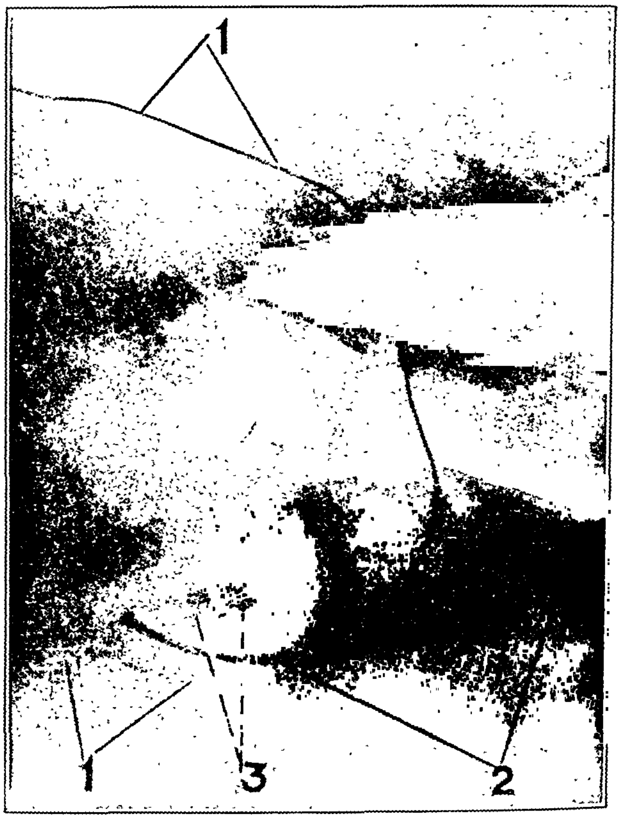
Frequent nocturnal emissions (even in married men), the "hair-trigger" premature emission, and hematospermia are common results of chronic prostatovesiculitis. Extension of chronic infection to the epididymis results in thickening of this tube and chronic hydrocele, which is especially common in elderly men.[9] Extension to the testis induces the sclerosis of that organ studied by Ries,[10] which results in azoöspermia.

Impotence and sterility are especially frequent and important results of pus infections of the seminal tubes. Impotence, when not due to spinal-cord disease or diabetes, is commonly the result of prostatovesiculitis, and is for a long period amenable to intelligent local treatment, though refractory to the routine administration of phosphorus, strychnin, electricity, etc. Sterility may result not merely from mechanical occlusion of epididymes or vasa, but also from infections of the seminal duct, the spermatozoa being non-motile or disintegrated, but regaining form and motility after these infections have been abolished. In fact, the entire pathology of functional derangements and so-called neuroses of the male sexual organs becomes intelligible only through a study of the infections of the seminal ducts. It is well known clinically that early impotence has been sometimes relieved by massage of the prostate, though this is but a crude means of treating chronic prostatovesiculitis; to more efficient methods this hitherto refractory affection is more frequently amenable; for "chronic prostatitis," so-called, notoriously refractory to standard therapy, is usually prostatovesiculitis, needing treatment directed to the vesicles as well as to the prostate.

SURGICAL TREATMENT

The Vesicle.—Incision of the suppurating vesicle from the perineum was made by Lloyd (1889); Dittel, the father of perineal prostatectomy, used his dissection to expose and incise the vesicle (1894). This operation has been improved and used by Fuller[11] in over 100 cases. It is bloody, imperils the integrity of the rectum, but has been in his hands devoid of mortality.

Injection of the vesicle through the ejaculatory duct was first performed in the living subject by Klotz,[12] who introduced the nozzle of a special syringe through the endoscope into the urethral end of the ejaculatory duct, and injected liquid into the vesicle. Epididymitis promptly followed, [illegible]cing infected material through the [illegible] or sounding of the ejaculatory duct has been rendered feasible by the modern irrigation urethroscopes of the Goldschmidt pattern. Yet in practical utility I have found this measure far inferior to vasostomy, which, moreover, involves no expensive instrument, technical skill, injury to verumontanum or ejaculatory ducts, or epididymitis.



Radiogram of median section of male pelvis, showing relation between urinary and seminal ducts in the broad ligament, and accessibility of both through a perineal incision; 1,1, wire in vas deferens; 2, probe in ureter; 3, terminal phalanx of first finger, resting on the seminal vesicle.

The Epididymis.—Early in the last century the infected epididymis was punctured by Vidal and others, not for the evacuation of pus, but for the relief of tension. Incision of the non-fluctuating epididymis and tunica vaginalis was introduced independently by Escat[13] and by Belfield,[14] the latter using the incision to inject vas and vesicle at the same time. The epididymis incision has been advocated by Bazet and by Hagner also. But since non-tuberculous infections reach the epididymis by way of the vesicle and vas, acute suppuration of the epididymis proves existing infection of the vesicle; obviously, then, the latter should be drained and medicated by opening the vas (vasostomy) whenever the suppurating epididymis is incised. To incise the epididymis and neglect the infection persisting in ampulla and vesicle seems scarcely rational.

The advantages of this procedure over the medical treatment of epididymitis are: (1) shortening the period of pain, fever, swelling and confinement; the patient is ready to resume ordinary avocations in three to five days; (2) avoidance of the usual chronic, tender induration in the tail of the epididymis, which sometimes contains pus and gives rise to recurrent epididymitis. Whether the chance of permanent occlusion of the epididymal canal is increased or diminished by the incision itself remains for larger experience to determine. Moreover, the intelligent use of vaccine therapy distinctly diminishes the frequency and the severity of gonorrheal epididymitis and correspondingly restricts the field of the epididymis incision.

Vasostomy.—Four years ago[14] I published the method of draining and medicating vas, ampulla and vesicle through an incision into the vas (vasostomy) and extending the incision into the epididymis when the latter contains pus. I have now opened the vas 149 times in 107 patients, usually in the office under cocain anesthesia, often without assistance.

By this trivial operation the entire duct—a closed abscess—is relieved of pus tension, vas and vesicle are drained and medicated, the epididymis is protected from infection or, if already infected, from pressure infection, for pus drains through the vas incision from the epididymis also. Medication of the ampulla and vesicle is effective because the injected solution remains in their cavities for days; thus, after injection of the vesicle with argyrol solution, a nocturnal emission two nights later was so black as to frighten the patient into the fear that his future children would be negroes.

Many cases refractory to standard treatment, including "chronic cystitis," "irritable bladders," gleet, admixture of blood with semen, premature ejaculation, recurrent epididymitis, have been promptly relieved.[15] In certain other conditions, notably the pelvic pain due to perivesiculitis, the operation has failed to afford relief. Its utility is measured by the accuracy of diagnosis.

In two cases in which injection of the vesicle was prevented by a stricture of the vas, the occluded portion of the vas was excised and the cut ends anastomosed, restoring the lumen of the canal. In one of these a chronic "neuralgia of the testis," apparently caused by distention of the epididymis with spermatozoa, vanished after the natural exit was restored through this resection.

In the technic of vasostomy three features are important: (1) fixation of the vas, which otherwise may drop into the scrotum and be recaptured with difficulty; (2) raising the vas through the skin-cut for accurate manipulation; (3) exploration of vas for obstruction by sounding with a silkworm thread. Details may obviously be varied at the discretion of the operator. When resection of the vas is performed, a silkworm of catgut thread is passed into the lumen and out through the wall of each cut end and the ends tied above the skin, the thread serving as an axis splint which secures exact apposition of the cut ends of the vas. This method of anastomosis, first published by Mayo,[16] supersedes all other methods of reuniting the divided vas. Incidentally I have observed that after resection of a half inch of the vas the cut ends have reunited spontaneously with a patulous lumen. This is important to remember.[17]

Pelvic abscess in the male, anterior to the rectovesical fascia, is a frequent extension from infected appendices, seminal ducts or lymph-glands; it may open spontaneously into the rectum, sometimes indeed undetected. When recognized, pelvic abscess may be incised from the rectum, provided bulging is felt there; otherwise through the ischiorectal fossa or the triangular ligament (the ischiobulbar triangle). Two years ago I opened a large pelvic abscess, which proceeded from an infected vesicle, through a curved incision beginning in the median line three inches above the symphysis and carried downward and outward above Poupart's ligament. The curved flap was turned upward, the rectus pulled toward the median line and abscess and vesicle reached by blunt dissection; drainage was secured through the perineum. This curved incision exposes also the juxtavesical portion of the ureter, perhaps as well as does Israel's iliac or Gibson's[18] flap incision.

VACCINE TREATMENT OF PUS TUBES

The frequent failure of vaccine therapy against infections of the male genital tract is undeniable; its occasional spectacular success, unknown through other means, is equally indisputable. The successes warrant the suspicion that the failures are not the fault of the principle but of the efforts to apply the principle—in other words of inaccurate treatment.

My own experience has been a steady improvement, from customary failure especially with stock vaccines, to customary benefit especially with autogenous vaccines, against infections of the seminal duct by the tubercle bacillus, gonococcus, staphylococcus, streptococcus and colon bacillus. Against these infections accurate vaccine therapy impresses me as the most valuable of all constitutional aids to local treatment.

SUMMARY

1. Pus infection of the seminal tract plus occlusion of the ejaculatory duct soon converts vesicle, vas and finally epididymis into a closed abscess.
2. Vasostomy is the simplest and least objectionable means of evacuating pus, relieving tension and medicating vas and vesicle.
3. Among the effects of these infections on the urinary organs are bladder iritation and obstruction of the ureter with consequent kidney lesions.
4. Impotence, sterility and sexual neuroses in the male are frequent results of pus infections of the seminal tract and amenable to appropriate treatment thereof.
5. Vaccine therapy, accurately applied, is the most valuable internal measure against the infections which produce pus tubes in the male.

[15] The value of vasostomy in relieving recurrent epididymitis was shown in eleven cases reported to the recent German Urological Congress by Picker (Ztschr. f. Urol., 1909, No. 6).

[16] Mayo: Ann. Surg., January, 1895; this publication has been ignored by certain later writers.

[17] The sterilization by vasectomy of confirmed criminals, imbeciles and other defectives, already performed in Indiana on a thousand convicts, is generally approved wherever the public has been taught by physicians that vasectomy, unlike castration, does not unsex a man, does not impair his sexual power. Its effect is merely that of occlusion from bilateral epididymitis. As these defectives have increased twice as fast as has the total population, this simple method of checking their propagation seems worthy of general attention.

[18] Ann. Surg., 1908, p. 445.

may, therefore, bind and obstruct the adjacent ureter. Morgan[7] found exactly this condition on exploratory operation, and cured the patient by liberating the ureter from its adhesion to the vesicle; and Young[8] later reported a similar case in which adhesions to the vesicle had produced occlusion of the ureter and destruction of the kidney, compelling nephrectomy.

As Tandler and Zuckerkandl note, the ureter dilatation incident to prostatic hypertrophy occurs above the point where the ureter is crossed by the vas deferens, and is obviously due to pressure by the latter; hence division of both vasa should be a part of surgical attempts to relieve the results of such hypertrophy, when renal retention exists.

This intimate relation between the juxtavesical ureter and the seminal duct seems, therefore, responsible for considerable kidney and ureter disease hitherto unexplored.

Renal pain—"lumbago" or "nephralgia"—often occurs when the vesicle is distended, and is promptly relieved by emptying the vesicle either through massage or vasostomy. Apparently simple distention of the vesicle may compress the ureter and thus distend the renal pelvis.

IMPOTENCE AND STERILITY

The juxtaposition of the seminal ducts to bladder and rectum renders the relation of pus tubes to vesical and rectal tenesmus sufficiently obvious. The abdominal pain from an infected vas simulates that of ureteral calculus and of appendicitis, and in at least one instance led to a mistaken diagnosis and futile operation for appendicitis by a competent surgeon. The "neurasthenia" caused by prostatovesiculitis, commonly explained by an obscure nervous influence, seems rather a toxemia from the local infection: for it is often relieved by evacuation of pus from the genital tract.

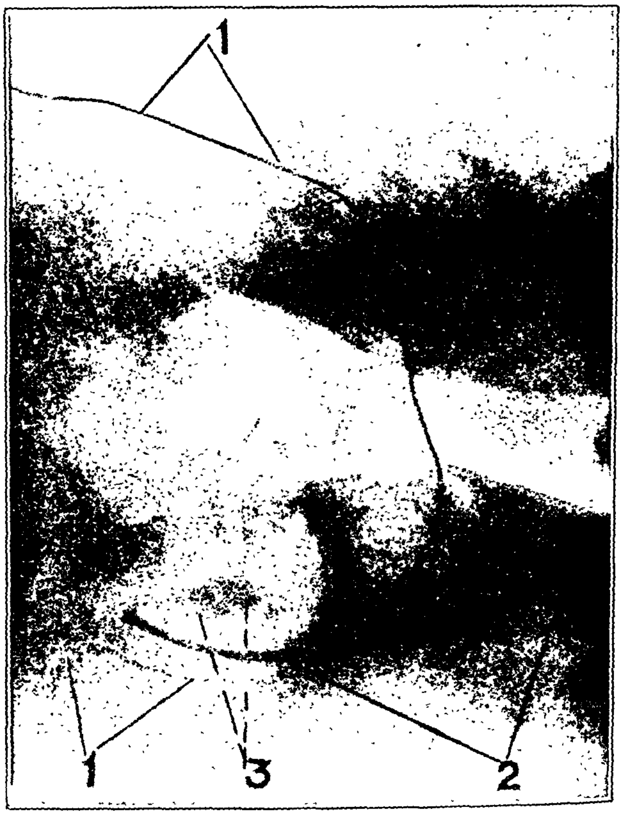
Frequent nocturnal emissions (even in married men), the "hair-trigger" premature emission, and hematospermia are common results of chronic prostatovesiculitis. Extension of chronic infection to the epididymis results in thickening of this tube and chronic hydrocele, which is especially common in elderly men.[9] Extension to the testis induces the sclerosis of that organ studied by Ries,[10] which results in azoöspermia.

Impotence and sterility are especially frequent and important results of pus infections of the seminal tubes. Impotence, when not due to spinal-cord disease or diabetes, is commonly the result of prostatovesiculitis, and is for a long period amenable to intelligent local treatment, though refractory to the routine administration of phosphorus, strychnin, electricity, etc. Sterility may result not merely from mechanical occlusion of epididymes or vasa, but also from infections of the seminal duct, the spermatozoa being non-motile or disintegrated, but regaining form and motility after these infections have been abolished. In fact, the entire pathology of functional derangements and so-called neuroses of the male sexual organs becomes intelligible only through a study of the infections of the seminal ducts. It is well known clinically that early impotence has been sometimes relieved by massage of the prostate, though this is but a crude means of treating chronic prostatovesiculitis; to more efficient methods this hitherto refractory affection is more frequently amenable; for "chronic prostatitis," so-called, notoriously refractory to standard therapy, is usually prostatovesiculitis, needing treatment directed to the vesicles as well as to the prostate.

SURGICAL TREATMENT

The Vesicle.—Incision of the suppurating vesicle from the perineum was made by Lloyd (1889); Dittel, the father of perineal prostatectomy, used his dissection to expose and incise the vesicle (1894). This operation has been improved and used by Fuller[11] in over 100 cases. It is bloody, imperils the integrity of the retum, but has been in his hands devoid of mortality.

Injection of the vesicle through the ejaculatory duct was first performed in the living subject by Klotz,[12] who introduced the nozzle of a special syringe through the endoscope into the urethral end of the ejaculatory duct, and injected liquid into the vesicle. Epididymitis promptly followed, presumably from forcing infected material through the vas. Catheterization or sounding of the ejaculatory duct has been rendered feasible by the modern irrigation urethroscopes of the Goldschmidt pattern. Yet in practical utility I have found this measure far inferior to vasostomy, which, moreover, involves no expensive instrument, technical skill, injury to verumontanum or ejaculatory ducts, or epididymitis.



Radiogram of median section of male pelvis, showing relation between urinary and seminal ducts in the broad ligament, and accessibility of both through a perineal incision; 1,1, wire in vas deferens; 2, probe in ureter; 3, terminal phalanx of first finger, resting on the seminal vesicle.

The Epididymis.—Early in the last century the infected epididymis was punctured by Vidal and others, not for the evacuation of pus, but for the relief of tension. Incision of the non-fluctuating epididymis and tunica vaginalis was introduced independently by Escat[13] and by Belfield,[14] the latter using the incision to inject vas and vesicle at the same time. The epididymis incision has been advocated by Bazet and by Hagner also. But since non-tuberculous infections reach the epididymis by way of the vesicle and vas, acute suppuration of the epididymis proves existing infection of the vesicle; obviously, then, the latter should be drained and medicated by opening the vas (vasostomy) whenever the suppurating epididymis is incised. To incise the epididymis and neglect the infection persisting in ampulla and vesicle seems scarcely rational.

TRUE TIC DOULOUREUX OF THE SENSORY FILAMENTS OF THE FACIAL NERVE

I. CLINICAL REPORT OF A CASE IN WHICH CURE WAS EFFECTED BY PHYSIOLOGIC EXTIRPATION OF THE GENICULATE GANGLION *

L. PIERCE CLARK, M.D.

II. REPORT OF SURGICAL TREATMENT

ALFRED S. TAYLOR, M.D.
NEW YORK

I. CLINICAL REPORT AND REMARKS BY DR. CLARK

It has been fairly well proved by recent investigation that the facial nerve, like the trifacial, is a mixed nerve. Its sensory ganglion is the geniculate. The motor root of the geniculate is the facialis proper, and its sensory root is the nerve of Wrisberg. Below the ganglion the peripheral divisions are the facialis proper, the greater and lesser superficial petrosal, external petrosal and chorda tympani. This ganglion is of the spinal type, consequently liable to inflammations, as herpes zoster, and degenerations, as in tic douloureux. The zoster zone of the geniculate lies just in the interior of the auricle and external canal. This zone is interposed between the zone for the Gasserian in front and the cervical behind. In either zoster or neuralgias we may have one or all three zones affected at once. There is also a considerable degree of overlapping in these three zonal areas, so that a diagnosis of a definite lesion of one zone is often a clinical nicety not easily attainable. Varying clinical syndromes of inflammation and degeneration of these zonal areas have already been described in literature (Hunt).

More accurate studies in the anatomic areas involved in the otalgias will probably show that not a few of these neuralgic disorders are derived from disease of the sensory fibers of the facialis, either in the roots or ganglion, or both. Indeed, it is logical to think of the geniculate sensory system and its disorders as analogous to those of the Gasserian of the trifacialis. What the geniculate system may lack in clinical importance in its smallness of peripheral distribution may be compensated for by the complexity of its ramifications and associations with adjacent sensory systems.

No doubt the complexity of the sensory system in and about the ear is largely responsible for the bewildering array of reflex and idiopathic otalgias. Text-book descriptions of the otalgias are but repetitions of our earlier knowledge of trigeminal neuralgias. Our modern understanding of the latter but points the way in which the idiopathic otalgias must be studied and analyzed. While the reflex causation of the idiopathic otalgias probably has a somewhat better basis in actual material than have facial neuralgias, one cannot help being impressed with the idea that carious teeth have been overcharged with responsibility, and that dental obsessions are as keenly in evidence here as eyestrains and the like defects in the visual apparatus for trigeminal neuralgias. The apparently quick relief of idiopathic otalgias by tampering with the teeth, throat or nose may be explained by the more or less certain self-limiting course of acute posterior poliomyelitis. In other words, the evidence of cure of idiopathic otalgias by various operative procedures in the throat, mouth or nose is no better than that of cure by similar operations on the eyes or nose in idiopathic facial neuralgias. Many otologists do not hesitate to say that what we now know to be a genuine posterior poliomyelitis shown in classic herpes zoster is due to irritation of a carious tooth. There can be no doubt that a reflex cause for idiopathic otalgias may be, and indeed is, found in disease of the teeth, throat and nose, but that these peripheral sources have been overestimated there can be no doubt.

The difficulty of disentangling that form of idiopathic neuralgia of geniculate ganglion disease which immediately concerns our purpose is at present due to a separation of that otalgia which is confined to the anterior wall of the external auditory meatus and the skin just in front of the ear. As is well known, this area is supplied by the auriculotemporal branch of the trifacial as well as the sensory filaments of the geniculate ganglion. More rarely it is supplied by the second branch of the trifacial. The absence of tenderness and pain in the other divisions of the first branch of the trifacialis should exclude this sensory system from involvement. This is not always easy to determine when, as often happens, there is reflex involvement in the trifacial. Usually, however, the reflex disturbance in the trifacial, as well as that in the cervical nerves, can be eliminated by appropriate antineuralgic treatment. There is no reason to think that the prognosis or treatment of idiopathic otalgia of the geniculate system should be different from that of the trifacial. Once the diagnosis is made and the usual antineuralgic remedies have been tried, operative interference is indicated. There is but one procedure practicable—that of physiologic extirpation of the geniculate ganglion, a division of the posterior root of the ganglion, the nerve of Wrisberg.

I will give in brief the history of a case of tic douloureux of the sensory filaments of the facialis and its outcome as follows:

Patient.—Mrs. E. T., aged 28. Aside from the history of morphinism, contracted since the neuralgia began, the family and personal history previous to present illness are negative.

Present Illness.—In February, 1907, the patient experienced paroxysmal, intermittent pain without known cause, just in front of the left ear. The pain occurred for half an hour almost weekly. Two months afterward the pain in front of the ear was of daily occurrence of a typical neuralgic character, sometimes lasting for two and three hours. In the following October, eight months after the onset, the pain had increased constantly so that there was not only a stabbing pain in front of the ear, but also a steady pain in the depths of the ear, on the anterior wall of the external meatus. At times there was a moderate degree of neuralgic pain in all three distributions of the trifacial and in the occipital region. The latter distribution of pain in the trifacial and occipitocervical nerves decreased in five or six months, was intermittently present during the following year, but was never so severe as in front of the ear and in the anterior wall of the external meatus. The patient was taking about twelve grains of morphin daily when I first saw her. Hygienic and electrical treatment very soon removed all the neuralgic pain except that in the region of the ear. All ear, eye and throat and general medical examinations proving negative, the conclusion was unavoidable that the lesion was a true tic douloureux of the geniculate system of the facial nerve, and that the proper remedy was a physiologic extirpation of the ganglion, which I recommended. Later I learned that Dr. Starr had practically come to the same conclusion and recommendation.

The operation was performed at the New York Hospital by Dr. Taylor, April 23, 1909. Dr. Taylor will give the details concerning the operation which he performed.

Postoperative History.—Immediately after the operation all pain ceased. The patient had some ataxia, cerebellar in type, which steadily improved. The hearing, slightly impaired at first, owing to slight damage of the acoustic, was reported normal by an otologist one week after operation. The division of the facialis has given us a complete peripheral palsy which we trust will undergo spontaneous recovery in time; if not, a faciohypoglossal anastomosis may be undertaken. A slight redness of the external auditory meatus at the junction of the anterior wall with the tympanum, observable before operation, has since disappeared. All sensory examinations of the face and external ear proved negative three days after operation. The former area of pain seemed to the patient to be a little less sensitive in the tests. Since the operation patient has reduced her morphin from twenty-five grains to about six or eight grains daily. A steady withdrawal is in progress.

---

* Read at the Thirty-fifth Annual Meeting of the American Neurological Association, May 27-29, 1909.

To summarize: We have here a true tic douloureux of the sensory filaments of the facial nerve, apparently cured by a physiological extirpation of the geniculate ganglion.

Note.—Oct. 10, 1909: Examination of the patient to-day, a little more than five months since the operation, shows the following: The patient has had no pain in the ear; hearing is nearly, if not, quite normal and the conjunctival dryness on account of the facial palsy is much less troublesome. The normal muscle tone of the paralyzed face is present and slight but distinct voluntary contraction in the face is observable at the superior and inferior angle of the mouth and in the zygomatici and buccinator muscles. The electrical reactions have improved. Reaction of degeneration is no longer present and faradic response is obtainable in the before-mentioned muscles that show voluntary power about the mouth. The cerebellar ataxia is no longer present.—L. P. C.

II. REPORT OF SURGICAL TREATMENT BY DR. TAYLOR

This case was referred to me by Dr. Clark with the request that the geniculate ganglion itself be removed. A brief study on the cadaver showed that the ganglion could be removed, but that, from its close anatomic relations with the cochlea, the semicircular canals, the carotid artery and the motor trunk of the facial nerve, irreparable damage would probably be done to any one or all of these structures.

After reading the very convincing exposition of Dr. J. Ramsay Hunt, which demonstrates the geniculate ganglion and the "pars intermedia" to be the sensory mechanism of the seventh cranial nerve, the idea suggested itself to me that the sensory root might be divided in the posterior fossa of the skull. Numerous trials on the cadaver proved the feasibility of the operation. The technic so developed was then demonstrated to Dr. Clark, who consented to its trial upon his patient.

The patient had been told frankly that the operation was experimental. Her suffering had been such that she was anxious to have it done.

Operation.—On April 23, 1909, operation was done under ether anesthesia administered by Dr. George M. Creevey, whose method worked so admirably as to deserve special mention. Rubber tubes, passed through the nares to the laryngeal entrance, were connected to a single tube which ran to the etherizer, who was thus able to get out of the way of those working at the operative field, while keeping track of his patient by means of the radial pulse.

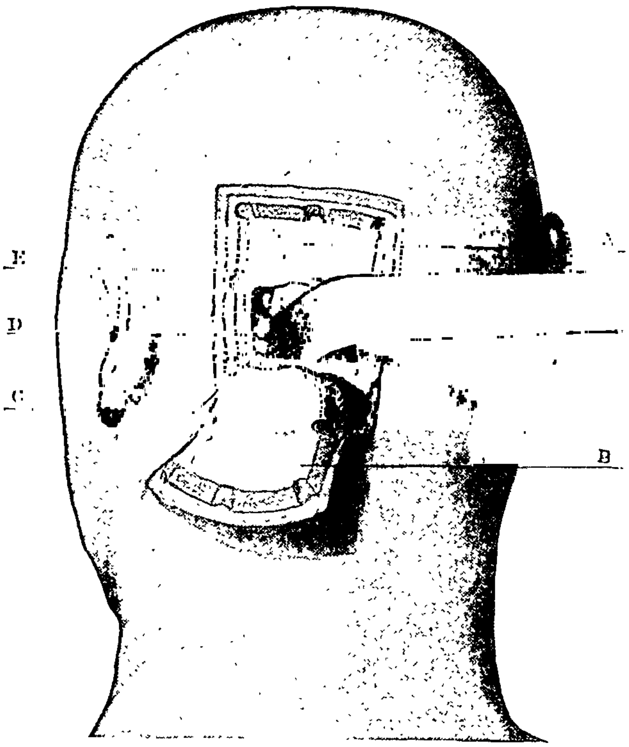
The patient was prone on the table with cushions under the upper part of the chest and shoulders and the head hanging forward so as to give a good exposure of the operative field.

An osteoplastic flap was turned down. Its outer edge was just within the posterior border of the left mastoid, the upper border about 2 cm. above the line of the lateral sinus, and the inner border just to the left of the median line. The lower, or hinge border, was well down toward the foramen magnum. When the flap was turned down the dura was tense everywhere. A dural flap was cut with its base turned toward the median line, its upper edge just below the lateral sinus, its outer and inferior edges just within the corresponding bone edges. The cerebellum protruded at once. A flat blunt retractor was passed to the outer side of the cerebellum to the base of the petrous bone, along which it was gently pushed, retracting the cerebellum, until the cerebrospinal fluid at the base of the brain escaped in considerable quantity with a rush. Immediately the cerebellum retracted easily and the nerve field was exposed. At this time the left shoulder jumped several times and it was found that the end of the retractor was resting against the ninth, tenth and eleventh cranial nerves as they were passing through the posterior lacerated foramen. (Illustration, C.) Just above and to the inner side of these was found the internal auditory meatus with the nerves sought. (Illustration, A.) The seventh, the pars intermedia, and the upper fasciculus of the eighth nerve were cut. The retractor was slowly withdrawn, allowing the cerebellum to return to its proper space. The dura was closed by a continuous catgut suture. The bone flap was laid back in place. The periosteum was sutured with twenty-day chromic catgut. The muscles were sutured with plain gut, and the skin with a continuous silk suture. A small drain passed from the surface of the dura, out through the lower left angle of the wound. Sterile dressings were applied and the patient returned to bed in good condition.

DISCUSSION OF TECHNIC

The flap was made large so that the cerebellum might be retracted easily and without undue compression. It was carried well above the lateral sinus so as to get bone thick enough to bevel and thus to be able to lay the flap back without bone sutures and without danger of its pressing on the brain. The inferior portion of the occipital bone is quite thin.

The bone flap was cut by the Hartley-Kenyon motor saw, which worked to perfection. The upper border and a part of the two sides were beveled so that the flap could be laid back without bone suture and still maintain its position perfectly. The dura was absolutely uninjured during the cutting and lifting of the flap.



Operation for the relief of true tic douloureux of the sensory filaments of the facial nerve. A, seventh cranial nerve, pars intermedia, fasciculi of the eighth cranial nerve (from above downward); B, osteoplastic flap; C, ninth, tenth and eleventh cranial nerves (from above downward); D, artery entering internal auditory meatus; E, lateral sinus just above the dural opening.

After the dural flap was made and the cerebellum retracted two things were found very useful; a suction apparatus working on the principle of the Sprengel pump which kept the field free from cerebrospinal fluid and blood; and a small cystoscopic bulb-light on a flexible stem, so that the light could be placed right in the operative field.

When the internal auditory meatus was exposed the nerves were seen entering it with an artery of moderate size. This artery was carefully retracted as it would have been rather troublesome to tie in a wound of such depth.

The seventh, the pars intermedia, and the upper fasciculus of the eighth cranial nerve were divided with a scalpel. The result was a complete left facial palsy, some temporary disturbance of hearing, and complete disappearance of the characteristic pain. This wide division was made for the following reasons:

It is known that, while most of them run in the pars intermedia, some of the sensory fibers may run with the facial or the upper part of the auditory nerve or both.

The very severe pain had rendered life a burden and had caused a morphin habit of twelve to fifteen grains a day which gave only partial relief. The patient was willing to have anything done that would relieve the pain.

This was the first operation of the kind ever done and it was absolutely essential to be sure that no sensory fibers remained.

To relieve the pain it would have been justifiable to divide every nerve entering the internal auditory meatus.

One of the very important features of the operation is the relation of the line of section to the trophic centers of the nerves involved. The motor portion of the nerve was divided between its trophic center and the periphery, and inasmuch as the ends lie right together, spontaneous regeneration with the return of power in the face may be expected. On the other hand, the pars intermedia was divided between its trophic center (geniculate ganglion) and the brain, so that an ascending degeneration of its fibers will occur; there will be no regeneration and the relief of pain will be permanent.

POSTOPERATIVE HISTORY

Facial paralysis of the left side was present on the operating-table and has persisted. On May 31 (five weeks and four days after operation) the asymmetry was distinctly less noticeable.

Wound Healing.—The sutures were removed on the fifth day, the drainage at the lower angle was discarded, the bone flap was in position, and the wound healed entirely by primary union. The head, which was shaved to a point only 3 cm. above the line of the lateral sinus, can now be entirely covered by dressing the remaining hair properly, so that the patient is not rendered conspicuous.

Pain.—There was considerable pain diffused over the entire left side of the head, but it was most marked in the region of the bone-flap, and, in and behind the left eyeball, there was severe stinging pain. After ten days these pains began to diminish and by the eighteenth day had all but disappeared. On the twelfth day the patient sat up in a chair forty-five minutes. That evening for two hours she suffered severe pain in the left ear which closely resembled the pains before operation. With that single exception she has never for a moment had anything resembling the old pain. Before operation the external auditory canal was very sensitive to touch. On the sixth day after operation she discovered that the finger introduced into the canal caused no discomfort, for the first time in many months.

Hearing.—For the first four days the left ear seemed to be absolutely deaf. From that time on hearing returned, and at the end of ten days seemed normal.

Vision.—Besides pain in the left eye, the patient complained of haziness in its vision. Examination developed nothing abnormal, so that it was attributed to the dryness of the conjunctiva due to the paralysis of the lids. Instillation of liquid petrolatum gave much relief.

Vomiting.—For many months the patient had been subject to vomiting attacks, especially after attempts to cut down the morphin allowance. After operation this tendency was aggravated and most troublesome. For six days after operation any attempt to turn on the left side or to turn the head to the left suddenly was followed by immediate vomiting. This symptom gradually disappeared. Ordinary vomiting has occurred at irregular but frequent intervals. She has gained ten pounds since leaving the hospital (May 13 to 28).

Morphin.—For the first five days the patient received about twenty-four grains in the twenty-four hours. From that time on it was much diminished, reaching a six-grain limit for the twenty-four hours at the time of leaving the hospital, which was the twentieth day after operation.

Miscellaneous.—On the fourth day the patient first mentioned a sensation as of flies or bees buzzing in the hair just above the left ear, and of a pricking sensation in the scalp of the same region. On May 2 (ninth day) these sensations had entirely disappeared. On attempting to walk (from the sixteenth day on) she complained of weak knees. She really has an ataxia of the lower extremities at irregular intervals.

THE TRANSPERITONEAL OPERATION FOR REMOVAL OF BLADDER NEOPLASMS *

E. S. JUDD, M.D.
Junior Surgeon to Saint Mary's Hospital
ROCHESTER, MINN.

The first case of intraperitoneal cystotomy was reported by Dr. Francis B. Harrington[1] in 1893. In this instance the operation was performed for ulcerative cystitis.

At this time cystotomy by any route was undertaken only in cases of extreme gravity. The mortality from suprapubic operations, operations through the perineum or urethra was not low; therefore, this apparently more serious procedure was not adopted by any great number of operators, and nothing more appeared in the literature concerning it until about a year ago, when Dr. C H. Mayo[2] reported five cases of transperitoneal removal of tumors of the bladder which were operated on in St. Mary's Hospital. A few months later Drs. Charles Scudder and Lincoln Davis[3] reported four cases in which bladder tumors were removed through an intraperitoneal cystotomy.

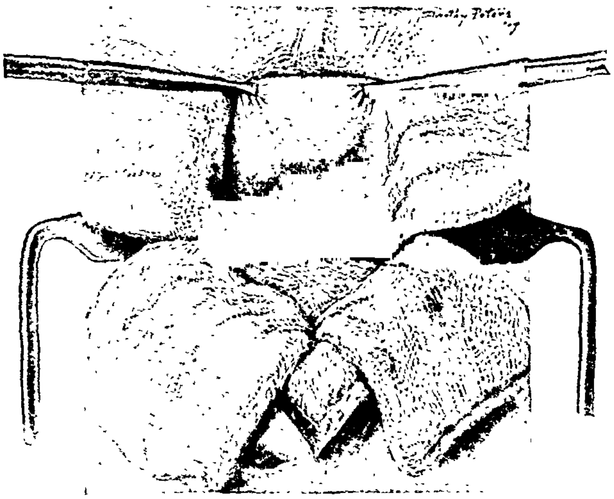

Fig. 1.—Bladder held up into abdominal wound which is spread open with Simpson retractors. Intestines, omentum and abdominal wound thoroughly protected with gauze pads.

One of the greatest difficulties with which earlier workers with lesions of the bladder had to contend was the diagnosis. This obstacle, however, was overcome more than twenty years ago by the invention of the cystoscope, and now in nearly every case a pathologic diagnosis can be made by first removing a specimen of the tumor with the cystoscope. By the aid of this instrument we not only learn the exact nature of the tumor, but we also learn its exact location and extent within the bladder.

Up to the present time the majority of reported cases of tumors of the bladder, both as regards operative mortality and early recurrences, have been very discouraging and some surgeons prefer not to operate in these cases except to relieve temporarily the symptoms of extreme pain or hemorrhage.

In December, 1905, Dr. Francis S. Watson[4] published a study of 653 cases. Combining operative deaths and recurrences under one heading, he found that failures occurred in 28.6 per cent. in benign cases and 46 per cent. in cases of carcinoma.

Delay in the diagnosis exposes the patient to the danger of an inoperable condition. Dr. Hugh Cabot[5] places the responsibility of such delay on the general practitioner who usually sees the patient first. He warns the practitioner against ever allowing a painless hematuria, which in the majority of instances is the first symptom, to go on while awaiting developments, because it is generally admitted that every papilloma, if not malignant in the beginning, will in time become malignant.

The greater bulk of tumors of the bladder with which we have to deal is made up of the papilloma and carcinoma types. Occasionally a myoma, myxoma, adenoma or angioma is seen, and not infrequently we see sarcoma in children.

During recent years there has been considerable discussion as to whether the papilloma is a benign or a malignant neoplasm. Some pathologists have concluded that the cells in the base of the pedicle are carcinoma cells, while others believe the tumors to be truly benign.

Although we seldom, if ever, see a recurrence at the site of the papillary tumor, it is common to encounter a return of the growth in some other section of the bladder. This may be accounted for by grafting on the mucous membrane from the first tumor, by extension through the submucosa, or by multiple lesions to begin with. From the standpoint of the patient, these tumors are certainly malignant and if not removed will cause death from persistent bleeding and extension. In a few instances, in fact in two of our cases at St. Mary's Hospital, an implantation of the cells occurred in the suprapubic wound through which the tumor had been removed, and a large and inoperable, rapidly growing, malignant tumor sprang up at this point.

Knowing that recurrences are nearly always local, and that extension to the glands and metastasis to other organs is very late, when the conditions do occur, and also that one of our greatest difficulties in handling a tumor of the base of the bladder, where over 90 per cent. of the lesions begin, is the inability to get a good exposure through a suprapubic or perineal incision, we determined to try to better former discouraging results by incising the bladder so as to get a good exposure of any part, and doing a more technical and radical operation. The first step is to make the incision into the bladder through its posterior wall near the base, in this way rendering all parts accessible. After closing the suprapubic incision in the bladder we have occasionally had the wound open and the urine drain for some time through this opening, but in no instance have we had leakage from the incision through the peritoneal surface, which is no doubt owing to the firmer and more rapid healing of the peritoneum itself.

Carcinoma with thick indurated base and open ulcer involving the entire thickness of the wall occurs less frequently in the bladder, but the only treatment that offers any permanent relief in either such conditions is a radical removal. The expert cystoscopist tells us the exact size and nature of the growth, also the position and extent of bladder involvement, and it is our endeavor to develop a method of approach and radical removal of the tumor. We must also develop a technic for caring for the injured bladder wall so that we may expect at least as good results as we are now obtaining in cases of similar neoplasms in other organs.

Previously our chief route of attack has been the suprapubic, and this does well in case the lesion is in the dome or superior anterior wall; the majority of these tumors, however, occur either in the base or lateral wall near the ureteral meatus.

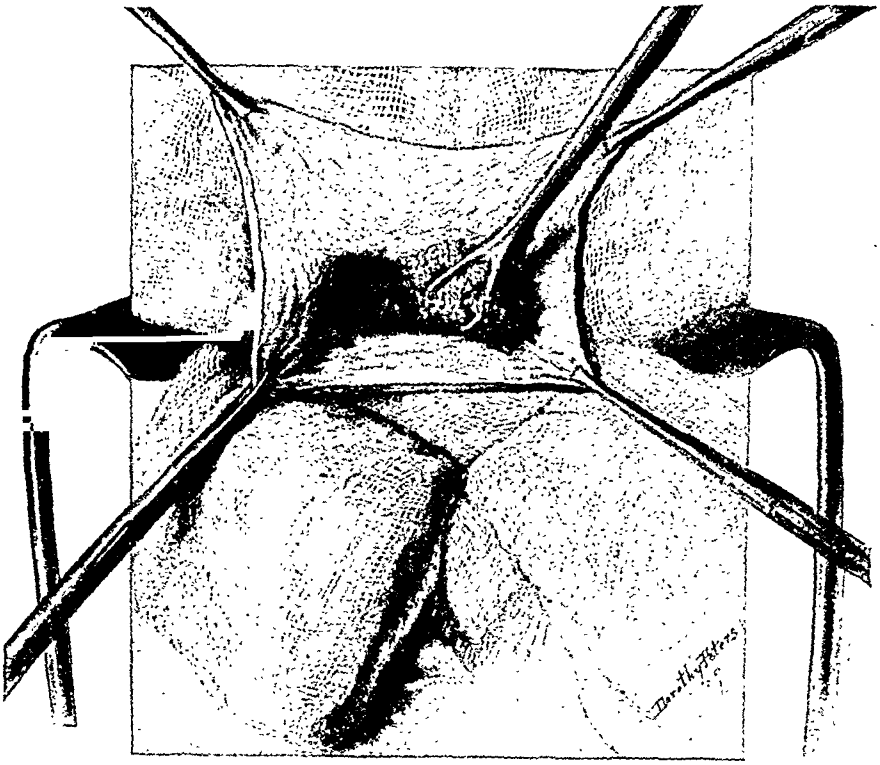

Fig. 2.—Tumor of base of bladder near right ureteral orifice. Incision held open by tacking forceps.

Profiting by the knowledge that the bladder has been accidentally opened many times during abdominal operations, and that the kidneys and ureters have often been exposed through a peritoneal incision without serious consequences to the peritoneum, we determined to open the peritoneal cavity deliberately and pack off the intestines and omentum, preparing this area of the peritoneal cavity for resection in the bladder, in a manner similar to that for resection of any organ.

The patient is placed in the high Trendelenburg position, and on opening the abdomen an opportunity is afforded for exploring the liver, pelvic peritoneum and lymphatics. Although we have never seen an extensive involvement of the lymphatics, in one case a metastasis had already occurred in the liver, and in another case the pelvic peritoneum was involved so that an intravesical operation would have been useless and harmful.

The intestines and omentum are packed into the upper abdomen with several large gauze pads, the packing covering the abdominal wound. The posterior bladder wall is grasped with tenaculum forceps, one on either side of the median line, and the bladder lifted into the abdominal incision. A longitudinal incision is made in the posterior wall of the bladder, beginning on its peritoneal surface in the midline and extending well back to the base of the bladder. The urine is sponged from the bladder as soon as it is opened. This should be done carefully so as not to start a troublesome oozing. If the tumor is on a pedicle, this may be grasped by a pair of curved hemostats and excised with a cautery, leaving the cauterized surface to granulate. The area removed should include a portion of the healthy mucosa and submucosa. When the tumor has an indurated base it will be necessary to excise a portion of all the coats. At times as much as one-half the bladder must be removed. It is essential to preserve as much as possible of the healthy tissue about the urethral orifice. If the bladder is involved at the ureteral opening, after the diseased portion of the viscus is removed, the ureter is divided near the bladder and drawn into the abdomen through a perforation in the peritoneum close to the remaining half of the bladder, into which it is passed and attached with catgut sutures. The peritoneum is closed over the exposed ureter in a fold, to insure rapid healing. The remainder of the bladder is closed, and, though greatly reduced in size, will be serviceable, and its capacity will tend to increase (Harris).[6]

---

[5] Cabot: New York Med. Jour., June, 1907.

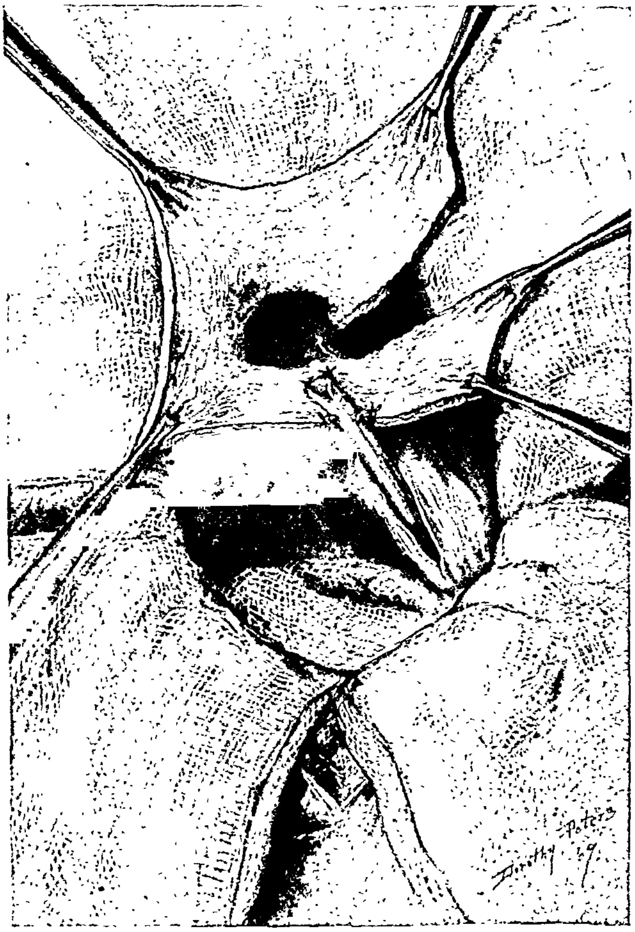

Fig. 3.—Bladder after excision of tumor including parts of bladder wall and right ureter. Ureter pulled through opening in peritoneum some distance from bladder and transplanted within the bladder wall.

Having completed the intravesical part of the operation, the same technic is employed in closing the wound in the bladder as that which would be used in repairing a wound in the *intestines* or stomach. The first row of sutures begins and ends with the knot inside. These are of chromic catgut placed as a running mattress or Connell stitch, including all the coats. The mucous edges are turned in, not only making an air-tight and water tight closure, but also controlling all bleeding from the edges. This suture line is re-enforced by a linen stitch, including the peritoneum, put in parallel to the previous suture line.

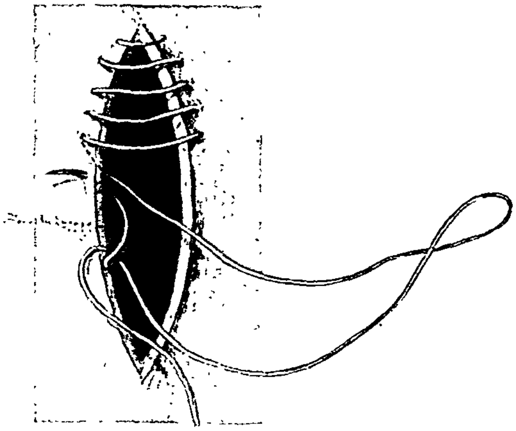

Fig. 4.—Method of closing bladder wound.

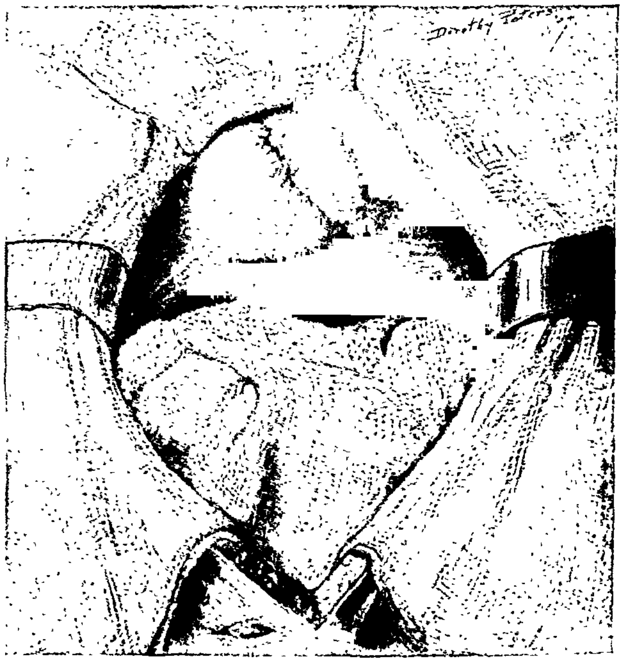

Fig. 5.—Operation finished. Entire incision and ureter closed over with peritoneum.

It is not necessary to drain the peritoneum or the bladder unless the growth involves the ureteral opening, or unless the prostate is removed, when it is best to establish an independent drainage through the space of Retzius after the bladder has been closed. As a rule, these patients void their urine frequently the first few days and are more comfortable without a catheter, though if spasmodic contraction persists in the bladder patients will be made more comfortable by small washings of warm boric acid solution to rid them of clots.

---

[6] Harris: Ann. Surg., July, 1902.

Employing this plan of procedure and technic, we have now operated in fifteen cases of tumors of the bladder with one death. In this case the patient was a man, 71 years of age, in whom the carcinoma involved nearly one-half of the bladder, including the left ureteral meatus. One-half of the bladder and the lower end of the ureter, which was greatly dilated, were removed. The excision included all the coats of the bladder wall. The end of the ureter was sutured into the remaining half of the bladder, and the bladder closed entirely. The patient voided urine freely and without aid for the first few days; then the amount gradually diminished, he became uremic and died at the end of the first week. There had been no leakage from the suture line or transplanted ureter, and the peritoneum was clean. The left kidney showed an old hydronephrosis with destruction of almost the entire parenchyma, and the right kidney was swollen and congested from an acute nephritis.

One patient, who had slight involvement of the pelvic peritoneum at the time of operation, died in three months of a recurrence in the peritoneum.

Six patients have lived over one year with no evidence of a return of the trouble. All except two of these patients (one complaining of frequency and one having a stricture which necessitated secondary operation) have been comfortable and apparently well.

One patient has been well ten months, one nine months, one five months and one one month. In this last case nearly one-half of the bladder was removed and the right ureter transplanted into the left half of the bladder. Since one week after operation the patient has passed clear urine. At first he voided very frequently, but the intervals gradually increased, and at the end of one month he averaged one or two times each night.

One patient with malignant papilloma returned in eighteen months showing a similar tumor in the opposite half of the bladder. This patient was reoperated on, and six months later a cystoscopic examination did not show any evidence of trouble.

One case of a large malignant papilloma in the left wall above the ureteral opening, ten months later showed no evidence of return in the old site, but there were many small pedunculated tumors growing from the margin of the urethral meatus. These were removed and the bases cauterized. The patient has been free from symptoms for four months. We were unable to trace two of the cases.

The size of these tumors varied from a few centimeters in diameter to a tumor in one instance occupying nearly the entire space of the bladder.

Four of the fifteen patients had more than one tumor. In nine the pathologist reported malignant papilloma. These included all the cases of multiple growths.

In three of the cases the pathologic report was papilloma, probably malignant.

Three cases were of the straight carcinoma type with indurated base involving the deeper coats and having the open ulcer on the mucous membrane surface.

Of the 15 cases, in 12 the trouble originated in some point of the base of the bladder, and in the remaining 3 it began in the lateral wall about one-half inch from one ureteral opening. In three instances the ureteral orifice itself was involved and it was necessary to transplant the ureter.

Although we do not advise or believe it necessary to go through the peritoneum in removing tumors in the upper quadrants of the bladder, our experience would lead us to believe that the greater number of neoplasms of this viscus begins in or near the base, and that we can, with very little if any greater risk to the patient do a much more technical and radical operation through the peritoneal incision.

EXTIRPATION OF THE UNOPENED HYDROCELE *

WILLARD BARTLETT, M.D.
ST. LOUIS

There is nothing new about a radical idea in the treatment of hydrocele of the tunica vaginalis testis; that condition which Virchow mentions as the most perfect example of exudation cyst. Almost fifty years ago Gross wrote on excision: "It is of the greatest antiquity, and was revived by Mr. Douglass, of England, in 1755." Since Gross' time various authors have written more or less concerning so-called radical treatment, but surgeons do not seem to have been actively interested in the matter until 1885, when von Bramann published the suggestion of Professor von Bergmann that the sac be excised. It was first to be opened and then its wall isolated as far as the testicle, or, in Bramann's own words, "bis an den Hoden," showing that a complete extirpation of the sac was not even attempted by the originator of the procedure.

Various authors state that there have been recurrences after even this excellent method, as there have after every other that has been proposed up to date. Hence it is not amiss to advance an idea which goes still further and obviates this possibility by disposing of every particle of excreting surface. This is most easily done with the sac intact; otherwise it is the old story over again; the leaving behind of a portion of cyst wall as in any other part of the body after accidental tearing of the same has occurred during its removal.

The following text-books on general surgery and surgery of the genitourinary tract make no mention of complete excision with the sac unopened: von Bergmann, von Brunns and von Mikulicz, Rose and Carless, Monod and Vanverts, Bryant, Kocher, Tillmanns, Fowler, Cheyne and Burghard, Zuckerkandl, Bickham, "American Text-Book," Gross, Vaughan, Pick, Koenig, Wharton, Keen, Dennis, Brewer, Esmarch and Kowalzig, Wyeth, Stewart, "International Text-Book," Watson and Cunningham, Casper, Bryant and Buck, Waring, Wharton and Curtis, White and Martin.

In addition to this Dr. Rassieur and Dr. Seelig, of St. Louis, have very kindly searched the literature for me, and, to the surprise of us all, found no reference to this very simple and logical idea. It surely must have been used; hence it seems strange that no publication of it can be found.

The technic of the operation is as follows: After turning out the sac in the ordinary manner it is easiest to begin its removal at the spermatic cord; the loose areolar tissue connecting these two structures can readily be separated by blunt dissection, as can the tumor from the testicle everywhere except at its lateral reflections from that organ, where some cutting must be

---

* Read in the Section on Surgery of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

done. No fluid need be lost, and one will be surprised *at the ease and quickness with which this dissection can* be accomplished. It must be stated, in passing, that quite a number of small blood vessels will have to be ligated. After the testicle has been replaced metal clips are placed on the wound in the scrotum so closely as to touch one another; they are quickly covered with powder and no dressing applied. The patient is up and about in four days, and the postoperative effects have differed in no wise from those immediately following other methods. I have tried this only on adults and in thin-walled cysts; it was contemplated on one baby, but was not carried out because I could not accurately locate the testicle before the sac was opened, and after that found it impossible to remove the visceral layer of serous membrane, i. e., to do more than the Bergmann operation. Perhaps the method would not be practicable in a very thick-walled tumor in which inflammation or severe injury had played a rôle. Puncture of the testicle is said to occur in emptying the fluid; this, too, could prevent the proper stripping of the surface of this member.

Removal of the unopened sac can truly be termed radical in the same sense as a Halsted or Bassini hernia operation, which removes the sac, as opposed to the Kocher operation, which brings a portion of the sac up through a split in the abdominal wall.

It is a little more difficult and takes a little longer to extirpate a hydrocele completely in the manner indicated, but it seems to guarantee the patient against a recurrence.

4257 Washington Boulevard.

[Editor's Note: The two preceding articles were discussed with that of Dr. Pederson, which, with the discussion, will be published next week.]

ALGID MALARIAL FEVER

WITH REPORT OF CASES *

THOMAS D. COLEMAN, A.M., M.D.
Professor of the Principles and Practice of Medicine, Medical Department of the University of Georgia; Visiting Physician to the Augusta City and Lamar Hospitals
AUGUSTA, GA.

The pernicious types of malaria are of absorbing interest because of their diverse clinical features and their high mortality. Complex problems are attractive, and a high death-rate in any disease is apt to stimulate the energies even of the slothful.

Pernicious malaria presents such problems, and their solution deserves the study of our best clinicians, for much more work is required to be done in their fuller elucidation. The term "pernicious malaria," while conveying an impression more or less definite, to the rank and file of the profession, and, therefore, to that extent serving a useful purpose, has none the less impressed me as being indefinite.

Perniciousness is a quality that may characterize any disease, and is doubtless dependent on a number of conditions. One might just as well speak of pernicious scarlet fever, pernicious measles, pernicious smallpox. Instead, however, we speak of malignant scarlatina, black measles, hemorrhagic smallpox.

CLASSIFICATION OF FORMS OF MALARIA

While these *qualifying* adjectives have in the main been inherited, and are not of the highest scientific value, they carry a sort of universal significance, which is, in a measure, understood. In this sense, therefore, certain types of malaria have been described in all languages—at least in all countries in which they occur—as pernicious. I think that the tendency on the part of some clinicians to subdivide minutely this class is as confusing as unnecessary.

For instance, I think one might just as well speak of the diarrheal form of typhoid fever, or of the constipated form of pneumonia, as the diarrheal or dysenteric form of pernicious malaria, as contrasted with the algid form. The simpler the classification of any disease the more effective it is. There is a type of malaria that is always serious and in many instances fatal. To this, for want of a better name, the term pernicious has been given, and is everywhere generally accepted.

From my study of the classifications of others and from my own experience with this type of the disease, I think that a subdivision into the comatose, hemorrhagic and algid varieties is all that is needed either for accuracy or elasticity. I have seen no variety that could not be placed under one of these subdivisions. A multiplication of them is, therefore, not only unnecessary but confusing.

With the term "pernicious" more or less definitely understood, it is interesting to inquire into the causes of pernicious malaria. It is generally conceded that this type is produced by the action of the estivoautumnal variety of the *Plasmodium malariæ*. Why, then, are some of the cases produced by them mild or benignant and others severe or pernicious? Unfortunately, we must depend here on analogy and our knowledge of the life-history of the parasite.

First, we may assume that a great number of the invading parasites, with the toxins secreted by them, is sufficient to bring about the pernicious symptoms. Against this it may be argued that in many fatal cases few parasites have been found. In such cases it may be and probably is true that the parasites have collected in the internal organs.

Second, it may be argued that in the severe cases either the parasites possess an unusual virulence or the resisting power of the individual has been lessened by preceding attacks of this or some other disease, or some vice of constitution.

Third, it may be supposed that the parasites, for reasons unknown to us, tend to accumulate in some portions of the anatomy, interfering with the circulation there and causing greater absorption of their toxins, and that the character of the attack varies according to the point of chief attack.

This is not unknown in the case of other organisms and has been actually shown in this. I refer to what has been described as an apparently unusual stickiness of the organisms and sluggishness of the circulation in the part.

It may be that a part or all of these factors are operative. At any rate they furnish a not unreasonable working hypothesis for the varying clinical pictures as we encounter them. For instance, when the cerebral cortex is invaded through its circulation we have the comatose variety produced. When the basal ganglia and medulla are chiefly attacked we have the algid variety. When a more general (even though in cases less active) invasion occurs we have great corpuscular destruction, and hemorrhagic malaria or blackwater fever results.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

All the pernicious forms of malaria are interesting, for they cry aloud for further study, but for the present our deliberations shall be limited to the algid type.

THE ALGID TYPE OF PERNICIOUS MALARIA

Algid malaria may be defined as a pernicious type of malaria, caused by the estivoautumnal form of the *Plasmodium malariæ* and characterized by profound prostration, cold and clammy skin, and an unclouded intellect; this latter in strong contrast with the comatose variety.

Geographic Distribution.—It occurs in all tropical and subtropical countries where malaria is found, occurring in Africa, Asia, southern Europe, the southern United States, Central America and South America. In predisposition, in age, sex and race, it does not differ from other forms of malaria. In subtropical countries it occurs chiefly in the late summer or early autumn and in all cases there is either the history or strong presumption that it has been preceded by other attacks of malaria; in other words, that it is a sequel or termination of a more or less chronic malaria, recognized or unrecognized. In all cases it is produced by the tertian and crescentic forms of the *Plasmodium malariæ.*

Pathology.—In cases in which autopsies have been performed, the pathology does not differ in any essential particular from that of other forms of pernicious malaria, with the single exception of hemorrhagic malaria, in which the urine is more or less surcharged with hemoglobin, giving to it its red and darkened color, and also its name, blackwater fever.

Symptomatology.—The symptoms of algid malaria are clear-cut and definite, and from them it gets its name. In some cases a definite malarial history will be elicited; in others the patient may not have been conscious of other malarial paroxysms, but he lives in a malarial section or has recently come from one.

The attack may be preceded by feelings of malaise, loss of strength, weight and appetite. A more or less torpid liver and constipation are also precursors, though more usually choleraic symptoms usher in the attack. The attack is often preceded by a more or less torpid liver and constipation. The immediate attack is ushered in by a chill or a general sense of chilliness and discomfort, in which event the chill is usually neither so decisive nor so long as in the intermittent variety. Following this there is a rise of temperature, which is usually not great; in most cases it is not present, and cases have been recorded in which the temperature remained subnormal.

The tongue is usually dry and coated and thirst is great. With the onset of the paroxysm pronounced nausea, vomiting and diarrhea set in. The general prostration is profound, and, while headache, pains in the back and limbs are usually present, they are not so marked as in many of the more benign varieties.

The facies is that of a patient suffering from cholera. The face wears a pinched look; the eyes are abnormally bright with hollows and circles around them; and, singularly enough, the brain remains abnormally bright even unto the end. The conjunctivæ and skin are often yellow. The skin is cold and clammy and shrivelled and almost constantly bathed in sweat, so that, to the touch, the patient feels as if he did not have any fever. It is this phase of the condition which gives to the disease its name. The mouth and rectal temperature may, however, show an elevation of temperature varying from 99 to 103 F. The pulse is small and thready and toward the end may be imperceptible. There is usually loss of appetite, and great thirst exists. The urine is usually scanty, high-colored and may show albumin and casts, but does not contain hemoglobin. The diagnosis is made from the history, which naturally includes the patient's past history, the presence or absence of cholera in the region and cholera morbus or ptomain poisoning. After all has been said, the diagnosis will necessarily hang on the blood examination or the autopsy; and even these may be misleading, for a patient may develop ptomain poisoning and still have been already infected with severe malarial poisoning. Cases for reasonable doubt, however, are exceptional.

Prognosis.—The prognosis is generally grave. In my experience the mortality has been, I regret to say, 100 per cent.

Treatment.—In all forms of pernicious malaria quinin seems singularly ineffective. I still adhere to the administration of quinin in the type under consideration, believing that it is a matter of the amount given and its subsequent absorption. For this reason I administer it hypodermically. The rest of the treatment is supporting and symptomatic.

REPORT OF CASES

CASE 1.—*History.*—H. D. V., white, aged 57, American, book agent, entered the City Hospital Oct. 13, 1902. His mother died of bilious fever, and one of his children died of malarial fever; otherwise the family history and personal medical history were negative. For about nine days previous to the patient's entrance into the hospital, he had been suffering from more or less nausea, vomiting, and swimming in the head, muscular weakness, and loss of appetite, which he attributed to the eating of some ham, which disagreed with him; following the nausea and vomiting, he developed diarrhea.

Examination.—On admission the patient was found to be a man of medium build, imperfectly nourished and anemic. The pallor of his skin was quite marked, the tongue coated and the conjunctivæ slightly tinged yellow. The lungs were normal, as was also the heart, except for diminished muscular power. The liver was slightly enlarged and the spleen considerably so. The skin was cool and clammy to the touch, being bathed in more or less profuse sweat; so that to feel the patient in any portion of his body, whether head, hands or feet, he seemed to be free from fever, and this continued steadily until the end. The temperature by mouth was 97.06 F.

Course of Disease.—On the next day the temperature rose to 98; then came a sudden drop to 93.06 at which time the patient developed a hiccough which persisted practically without intermission until his death. Nausea and diarrhea were pronounced. Following the drop in temperature there was a rise to 102.04 (by the rectum) although when the internal temperature was this high the surface was blanched, moist to the touch, and cool. Following this rise the temperature dropped to normal, and continued so until the morning of the fourth day. Just before death, the rectal temperature registered 100. The patient's mind continued unnaturally bright until the end. The case presented a picture not unlike that of Asiatic cholera, except for the fact that the stools were not so numerous or profuse. The diagnosis of algid malaria was made from the blood-smear, in which great numbers of estivoautumnal tertian organisms with crescents were found. Treatment was unavailing; at the beginning he was given broken doses of calomel at fifteen minutes' interval until he had received a grain and a half; he was given, hypodermically, ten grains of acid quinin hydrochlorid with urea three times a day, and a supporting treatment, including high salt enemas. Unfortunately, an autopsy was not allowed by the family.

I find a case recorded[1] by Dr. R. H. von Esdorf which presents many points of resemblance to the case just recorded by me, except for the more pronounced choleraic discharges in Dr. von Esdorf's case. Fortunately in that case an autopsy was thoroughly performed and recorded.

---

[1] Von Esdorf: Boston. Med. and Surg. Jour., June 18, 1908, clviii, 937.

Case 2 (von Esdorf's).—In brief there was a history of an illness of about six hours; symptoms of cholera, no fever, syncope and death.

Autopsy.—Enlarged liver and spleen; discolored mucous membrane of stomach; discolored mesentery and omentum, section of liver and spleen showed hemozoin in large and small masses, young small ring form of malarial parasites in red blood cells, lymphocytosis; free hemozoin in blood.

In a letter Dr. Rosenau makes this pertinent remark to Dr. von Esdorf, and the deduction seems reasonable: "He surely had an access of pernicious [malaria]. Don't you suppose, however, that he might have been sick on the trip, and that when you saw him he was suffering with the stupor due to the clogging of the capillaries of the brain with malarial pigment and parasites?"

Case 3.—*History.*—Mr. B., aged 60, white, traveling salesman, admitted to City Hospital, Oct. 16, 1902. His previous history was negative. On admission patient had severe bilious vomiting, copious diarrhea, and pains in stomach and intestines.

Examination.—The patient's temperature was 95 F. on admission and remained subnormal until death. The pulse was small and thready; respiration 28 to 40. The skin was cold, moist, clammy. The intellect was clear.

Course of Disease.—The patient was given acid quinin hydrochlorid hypodermically, Fowler's solution and a supporting treatment, but died on the third day. An autopsy could not be obtained.

For the report of the following case I am indebted to my friend, Dr. Murphy:

Case 4.—*History.*—John W., colored, aged 19, laborer in brickyard, was admitted to Lamar Hospital Sept. 26, 1902, in profound collapse.

Examination.—The patient was with a history of having had one chill eight days before admission, when diarrhea and nausea set in after a chill; conscious; his skin was cold and clammy; there was nausea, vomiting of green material, and copious watery diarrhea. The spleen was enlarged; the abdomen retracted; there was marked pallor of mucous membrane. Pulse was 124 to 126; temperature 97.8. Blood examination showed profuse infection with estivoautumnal ring forms, also a few crescentic and ovoid forms.

Course of Disease.—The patient was treated with calomel and magnesium sulphate after washing out stomach, and given acid quinin hydrochlorid gr. xv. hypodermically every three hours for three doses. Remittent fever set in after patient rallied from collapse, but yielded to treatment without any return of algid symptoms after twelve days.

Case 5.—*History.*—Susan Jones, colored, aged 56, laundress, was admitted to Lamar Hospital, August 1900, with history from family of "dysentery," with nausea and vomiting for three days. Coma had set in three hours before admission to hospital.

Examination.—The patient was unconscious on admission. Temperature was 98; pulse 108; respirations 20. Blood examination showed numerous pigmented leucocytes, but no intracellular parasites.

Patient sank into deeper and deeper coma and died nine hours after admission to hospital.

Autopsy.—This showed enlargement of liver two fingers' breadth below costal border, spleen just below costal border, dark red in color; capsule tense, soft in consistency; no changes of importance in other organs; liver and kidneys showed cloudy swelling. Smears from spleen showed enormous quantities of estivoautumnal parasites and pigmented cells, also much free malarial pigment.

503 Greene street.

ABSTRACT OF DISCUSSION

Dr. John A. Witherspoon, Nashville, Tenn.: While I do not practice in a malarial section of the country, I see much pernicious malaria in Nashville. The cases described by Dr. Coleman are comparatively rare and seemed to be those that are overwhelmed by the toxemia of malaria. Algid malaria, strictly speaking, is the type of malaria he described; in this type of the disease we find choleraic diarrhea, nausea, vomiting, colic, rice-water vomiting, purging and cholera. Fortunately, these cases are rare. In all malarial countries there are latent malarial cases; the infection invades the blood, especially of the spleen; the peripheral circulation may be examined carefully and no plasmodium found. Yet there is a low grade of infection and occasionally the temperature and chill will repeat themselves. Any man who undertakes to handle latent malaria should remember that it requires four or five months' constant treatment, and even then he may have relapses. One of the greatest mistakes a person may make in the treatment of this disease is to give quinin for two or three weeks and expect to cure the patient. Again, it should be borne in mind that these walking cases of latent malaria cannot be properly cared for while the patient is up and about his business. I have seen but two cases of the type described by Dr. Coleman. The first patient died one hour after I reached the bedside; the other lived thirty-six hours. Both patients were overwhelmed by the toxemia of malaria. The pupils were dilated, the rectal temperature was subnormal, the diarrhea was profuse and emaciation was rapid; yet the intelligence was perfect until the last. It is strange that with such a degree of prostration, with the pulse almost imperceptible at the wrist, the intelligence remained good. These patients rapidly became cyanotic and died in a state of extreme toxemia and exhaustion. It seems to me that the only hope for treatment in the type described by Dr. Coleman is to recognize the fact that the person has come to a malarial portion of the country, has come to an infected district where such severe forms of malaria develop, and that the only hope lies in trying to prevent the disease occurring. After the disease has developed, I believe that the only hope lies in the use of saline irrigations, transfusions and injections. I believe that the deep hypodermic injection of quinin, which gives such beautiful results in other forms of malaria, is absolutely useless here. Our only hope in curing these patients, I believe, rests in the intravenous injections of solutions of quinin. If the solution of quinin is injected into the tissues, into the muscular structures, the quinin will not be taken up by the circulation.

For those who are not used to giving quinin I should like to mention one practical point. I believe that quinin is used in too large doses. From 15 to 20 grains is sufficient in most cases, although I have given as much as 140 grains in three hours. But I insist on giving quinin hypodermically, putting it deep into the tissues. I cannot hope to get such good results by simply putting it under the skin. There will not be any abscess or irritation of the skin and the quinin will be better absorbed. Those men who have condemned the hypodermic method in the treatment of these cases did not use quinin in a proper acid solution and did not insert the needle deeply enough in the tissues. If I get another case of algid malaria I shall introduce the quinin into the veins. Some patients recover because of their strong resisting power, so it is said; but I think if they do recover it is by the grace of God.

Malaria throughout the South is decreasing; the number of cases occurring is growing less and less. Clearing up the swamps in certain districts has lessened materially the number of cases of pernicious malaria. The disease is now practically limited to the swampy districts; it is here that blood becomes contaminated after the individual has been put to sleep by the melodious song of the mosquito.

Dr. James B. McElroy, Memphis, Tenn.: I should like to speak about the classification of pernicious malaria and the treatment of the special form under discussion. The best classification probably is that given by Dr. Coleman, that is, comatose, algid and hemorrhagic. I think, however, that "blackwater fever" should be excluded from the latter. Blackwater fever differs from pernicious malaria in the mode of occurrence, in clinical manifestations and in parasitology. "Blackwater fever" occurs most frequently in old residents in malarial districts; pernicious malaria most frequently in children and newcomers to infected districts. In pernicious malaria, paroxysms occur at regular intervals of rarely less than twenty-four hours, and each paroxysm tends toward death. In hemoglobinuric fever the paroxysms usually come at shorter intervals, and, unless the first paroxysm ends fatally, death is not usually produced by the associated malaria. As a rule, pernicious attacks of malaria are associated with numerous parasites, with a tendency to increase with each succeeding paroxysm. Large phagocytes are also frequently seen. In blackwater fever parasites are few, and frequently absent; they tend to disappear early from the peripheral blood and internal organs as well; large phagocytes are seldom seen. While blackwater fever is most frequently of malarial origin, I do not think it should be regarded as a pernicious attack in the sense in which the comatose, algid and hemorrhagic are. The pernicious hemorrhagic group should be reserved for those pernicious attacks of malaria associated with real hemorrhages. The treatment best adapted for the algid forms is the prompt administration of quinin by hypodermoclysis in normal salt solution. The prognosis is always grave in these; but on several occasions I have seen recovery follow this measure in severe algid attacks.

Dr. Thomas D. Coleman, Augusta, Ga.: I should like to call attention to the fact that in the cases I have reported the duration of the disease was short. In one case the patient died within a few hours after the onset. No case lasted more than four days. The duration was short and, of course, the symptoms were correspondingly severe and pronounced.

I prefer the bimuriate of quinin with urea, from 10 to 15 grains to the dose, repeated as the symptoms require. I think that Dr. McElroy's point on blackwater fever is a good one. I have never approved of the term "blackwater fever."

THE NOTIFICATION TO THE HEALTH AUTHORITIES OF CASES OF ABORTION AND MISCARRIAGE *

MYER SOLIS COHEN, A.B., M.D.
PHILADELPHIA

Physicians are not permitted to disclose any information that they have acquired in attending a patient in their professional capacity and which was necessary to enable them to act in that capacity. Professional secrets belong to the patient and can not be disclosed without the patient's consent. It is but right and proper that information acquired for a specific and humane purpose should be put only to the use for which it was obtained. Many sick and injured persons otherwise would deceive their physician or forego medical attention altogether, especially if guilty of crime.

Exceptions to this rule, however, do exist. Whenever the interests of the people as a whole are paramount, the individual rights of the patient are set aside. In many states, for instance, physicians are required to report to the health authorities all cases of tuberculosis. In others before a marriage license is issued the absence of venereal disease must be certified to. All births must be reported, even when illegitimate, the name and address of the unfortunate mother being given in such cases, and that of the father also, when known. The question, therefore, is not whether the professional secret is inviolable, but under what circumstances it should be disclosed.

So far as I have been able to learn, nowhere is abortion or miscarriage a notifiable condition. Cases that end fatally come to the knowledge of the authorities through the death certificate, which under some laws must mention the fact when death is due directly or indirectly to this cause. A district attorney, however, speaking at a medical meeting, held that self-induced abortion should not be reported, whether the patient lived or died. In cases of criminal abortion some believe that a physician is not permitted to disclose any information he may possess, even on the witness-stand, whether the patient be living or dead. On the other hand, in some states a physician is compellable by law to testify in the witness-box—not voluntarily—what he knows indicating the commission of criminal abortion when the victim of that abortion is dead; but must keep silent when the patient survives and does not waive her privilege. In the latter instance some think that the physician should endeavor to procure the consent of the patient to inform the authorities, even though she survives. Others say that the law forbids only the disclosing of such information as is necessary to enable a physician to treat his patient, which does not include evidence of wrongdoing. It has been maintained, moreover, that a physician summoned to a case of criminal abortion has a duty to fulfil to the community, as well as to his patient. I would add that he also has a duty to himself.

Every physician who attends a case of abortion or miscarriage, whether accidental, self-inflicted, or brought on by another, lays himself open to the charge of having committed a criminal operation, especially if he had been in attendance on the patient previously. Should the woman die, suspicion points to him still more strongly and if a coroner's autopsy shows that a crime has been committed, he is placed in a decidedly awkward position. An innocent physician could easily be made the subject of blackmail.

It has been suggested that in all cases of suspected criminal abortion the general practitioner safeguard himself by calling in as early as possible another independent medical witness. But it is difficult to see how this would remove the suspicion. The consultant would have no personal knowledge as to how the abortion occurred. In fact, an abortionist could then avoid suspicion by merely calling in another physician, who even might be a fellow-criminal. And surely it is no less a breach of professional confidence to make known a patient's condition to a physician who is called in, not to assist in the treatment, but merely to protect the attendant, than to report the case to the health officer, the one who is responsible for the health and the vital statistics of the community.

Compulsory notification might act as a deterrent to the abortionist, as suspicion would naturally fall on those who fail to report their cases or who report a great many.

Undoubtedly vital statistics lack important data when they fail to include the number of abortions, miscarriages, and still-births. Such information is necessary to the study of the problems of fecundity, depopulation and race suicide, matters of the greatest importance to the nation.

Census reports would be more valuable, physicians would be protected, and crime discouraged if the occurrence of abortion or miscarriage were made reportable by law. On the other hand, no breach of professional confidence will occur if the name and address of the patient be not given, the location merely being indicated in a general way. Nevertheless I see no reason why the same procedure should not be followed that obtains when a birth occurs, namely, the reporting of the patient's name and address. This naturally should be regarded as a privileged communication, to be kept secret by the health officer or registrar, unless a good and sufficient reason exists for disclosing it.

---

*Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

Should the report contain more than the mere statement of the occurrence of the abortion? It might be advisable for the physician to give his opinion as to the cause, whether accidental or criminal, and in the latter instance whether self-induced or brought on by another. My own opinion is that no details should be given and no suspicions mentioned, unless the patient dies, in which event the attendant should be compelled to communicate all the information in his possession.

Who is the proper official to be notified? The coroner is suggested by most writers. That he should be informed when death ensues goes without saying. But there is a question in my mind whether he should be made acquainted with any cases except those ending fatally. I fail to see why convalescent and uncomplicated, accidental cases should be reported to the coroner, whose duty is to investigate the cause of death. Mere detection of crime properly belongs to the prosecuting attorney of the county. It would appear more fitting to report to this officer when a crime has been committed. But it hardly seems right to notify him in the absence of crime.

In my opinion, physicians should be required to report cases of abortion and miscarriage to the same official to whom they report all other notifiable conditions, namely, the health authorities. The health officer, who usually records the deaths and births and the existence of contagious disease in a community, should also be notified of the premature births, the still-births, the miscarriages and the abortions. He can then inform the coroner or the prosecuting attorney when in his judgment this seems indicated. In those states, however, where births and deaths are reported to a state or district registrar, it might be well to report to him all abortions and miscarriages.

It would, therefore, be well for the Committee on Legislation of this Association to urge the enactment of a law requiring the physician or midwife attending a case of abortion or miscarriage or still-birth to report such case to the proper health authorities or to the registrar, and if there be no attending physician or midwife, requiring the patient or her husband, or the householder or owner of the premises, or the manager or superintendent of a public or private institution in which the abortion or miscarriage occurred, to give such notice. This is the procedure followed in Pennsylvania in regard to infants born alive. Why should it not be applied to every product of conception that passes through the birth canal?

4102 Gerald Avenue.

ABSTRACT OF DISCUSSION

Dr. W. Forrest Dutton, Walker's Mills, Pa.: I regret to say that the bureau of vital statistics, as conducted by the state of Pennsylvania, is one of the greatest farces ever palmed off on an intelligent people. The physician is required, by law, to report all stillborn and other children; yet a midwife (of which there are very few in Pennsylvania licensed) or any other party can report these cases. Within the last few years hundreds of these cases have come to my notice which were never reported; and after the matter was reported to the state authorities they would write a few letters to these parties, and if these were not answered the prosecution was not carried any further. I think it would be a very good thing to have these cases reported; but unless we can get the laws changed and make them more forcible and see that they are carried out, I think it is only farcical and futile to try to attempt to secure any benefit by the registration of vital statistics, especially in Pennsylvania.

Dr. Marshall Langton Price, Baltimore: I should like to correct Dr. Dutton's misapprehension of the state of affairs in Pennsylvania. The registration area of the United States depends on the registration of births. Most of the state registrars have found it difficult enough to secure them in sufficient extent to meet the requirements of the census. There is not one of the seventeen or eighteen registration states that now registers births, with the possible exception of Massachusetts, and if Dr. Dutton were acquainted with the difficulties in the registration of births I think he would not be so severe in his criticisms of the Pennsylvania state authorities.

Dr. W. Forrest Dutton, Walker's Mills, Pa.: I may be a little warped, but, nevertheless, it is an exasperating fact that the state authorities arrest physician after physician who possibly has been so busy that he did not have time to register a case, and fine him from $75 to $100 for each case. It would be a different thing if the authorities were not informed that midwives and others do not report the births of children and were not told exactly where these people are located, yet they do not prosecute them.

Dr. Marshall Langton Price, Baltimore: What is the specific case to which you refer?

Dr. W. Forrest Dutton: The non-reporting of births and of stillborn children.

Dr. Marshall Langton Price, Baltimore: So far as I know, only one prosecution has been brought in the United States for the failure to register births, and that was in the state of Minnesota. I mean one successful prosecution. We have frequently all the evidence complete, and present it to the courts, and the courts fail to convict. Now, so far as I am individually concerned as State Registrar of Maryland, I intend to prosecute in the near future for failure to record births. I cannot promise now, or at any future time, that any of these prosecutions will be sucessful.

Dr. W. Forrest Dutton: Within a few months several physicians about Harrisburg have been prosecuted; but it seems an injustice to the physicians to prosecute them and not to prosecute the midwives. Especially people who take care of their own children should be reported.

Dr. J. N. Hurty, Indianapolis: Did I understand there is no place in the United States where accurate statistics of births are collected?

Dr. Marshall Langton Price: There is no registration area in the United States for the reporting of births except Massachusetts.

Dr. J. N. Hurty, Indianapolis: This is the second year we have collected birth statistics in Indiana. We believe we now secure records of within 2 per cent. of the births. This belief is based on a newspaper test. This test consists in taking all the newspapers published in the state, reading them, recording the births noticed therein and then seeing if the certificates have been received. All birth certificates come to the central office and we have found by this test that we receive 1.9 per cent. The doctors of Indiana are aiding the work splendidly. The Indiana State Medical Society passed a resolution strongly favoring the collection of birth records, and pledging its members to do all they could to make the work accurate. All but two or three county medical societies passed similar resolutions. In this way the profession is behind the work. Our trouble lies principally with the licensed midwives, and several of this class have been fined and their licenses taken away, because of failure to report births. There have been two or three successful prosecutions against physicians who have failed in their duty.

Dr. Marshall Langton Price: I am glad to hear this; because successful prosecution is absolutely essential to the recording of births.

Dr. J. N. Hurty, Indianapolis: While I am on the floor I wish to endorse everything that Dr. Cohen has said in his paper. It is an excellent paper. We should report to the coroner every suspicious death. The law requires this in Indiana.

DR. SENECA EGBERT, Philadelphia: I can, perhaps, explain to Dr. Dutton the reason for the rigidity of the Pennsylvania health authorities at present. If I am not mistaken, a few weeks ago a number (I think about six) of Philadelphia's physicians were reprimanded for failure to report births. This brought in a very large number of birth reports that had not previously been sent in. My recollection is, further, that none of those who were remanded were pushed to the extreme of the law's penalty. They simply were cautioned, and the result of the campaign was achieved, because the delinquent reports came in.

DR. W. M. BRUMBY, Austin, Texas: Our Texas state registrar has not been able to persuade our state and county authorities to follow the census bureau on the blank certificates of births and deaths, and the reports are by no means complete or accurate. I do not think, however, that we have had much trouble in some of our more essential features of vital statistics. I doubt very much the possibility of being able to get our people, or anybody else, to report on miscarriages, as recommended by Dr. Cohen. In a state where we have such a large percentage of ignorant people ushered into the world without any assistance, and out of it in the same way—no one officiating at either occurrence unless some old woman that we never heard of before—it is difficult to get reliable statistics. Our midwives do not take up that occupation until they reach the age of uselessness for all other purposes.

DR. W. H. DONALDSON, Fairfield, Conn.: I cannot allow to go unchallenged the statement regarding registration. Connecticut does not take a second place with Massachusetts, or any other state in the Union, in the matter of vital statistics. Registration of birth certificates, as well as death certificates and marriages, is as complete in Connecticut as in any state in the Union. I believe that we have a very high percentage. Of course, we do not get in every birth certificate; but we have an excellent health officers' law that has been in force for fifteen years, and I believe that there is a very complete registration of births, marriages and deaths. I do not propose to have Massachusetts placed ahead of us. Connecticut was one of the first to adopt registration and now stands well at the head. I could not get the idea of Dr. Cohen's reason for reporting all the cases that he suggests. As a health officer, I take opposite views with him. I do not believe it is possible, until we get nearer the millennium, to get all these cases. We are fighting for the reporting of tuberculosis and the contagious diseases. Now it is suggested that we have malarial diseases, abortions and all sorts of cases reported. We might as well stop specifying and say that all cases that come to our hands shall be reported to the health officers and the coroner. I do not believe that it is possible to secure the enactment of any such law, and the reporting of any such cases, and I doubt very much the benefit to be derived from it.

DR. MARSHALL LANGTON PRICE, Baltimore: It seems to me that the Germans have come nearer to recording birth certificates than any other nation in the world. There is a stub attached to the birth certificate which must by law be returned by the parent. The original certificate must be returned either by the midwife or the physician. If the parent's certificate is received and not the physicians, the authorities generally want to know the reason why, and a fine is very apt to be imposed on the offender. On the other hand, if the physician's certificate is received and not the parent's, the authorities likewise make inquiries, with practically the same result. If we could get out laws up to the German standard and use the double certificate it seems to me that the real solution of the problem would be reached.

DR. HENRY B. HEMENWAY, Evanston, Ill.: I was called many years ago to attend a young lady whom I had always regarded as a model of propriety. She was active in church work, etc.; there was absolutely nothing about her life, as I knew it, to lead to suspicion. The symptoms given were those, more particularly, that might point to typhoid. She stated that she had had her usual menstrual period one week before. She had a temperature of over 102 F.; there was a general abdominal tenderness, and slight tympanitis. In many ways the general symptoms were those of typhoid. I said that the case looked to me suspicious of typhoid. Later, by the merest accident, a note was left where I happened to see it—a note to a legal friend, and from a young man whom I had not the slightest reason to suspect knew this young lady; and the note read something like this: "Dr. Hemenway says my girl is threatened with typhoid. If the truth comes out, what shall I do?" I could read between the lines, and running through all the cases that I had seen I picked out this one case, and the next time I went there I sent the mother out of the room to get something and said to the girl: "You have had an abortion performed." The answer was: "Don't tell mother." Now, that case very likely would have got beyond control before I discovered what the facts were, if it had not been for that note. There was nothing at all in the history as I could get it, or in the examination as I made it, which would point to the actual facts, and if the girl had died under any such circumstances (she might have died very rapidly), it is more than possible that things might have looked very peculiar for me.

DR. MYER SOLIS COHEN, Philadelphia: Some one asked, what is the use of reporting cases of abortion? Three things would be accomplished. The first is the perfection of vital statistics. I saw the statement in a government report that in certain sections of the country the birth-rate is diminishing. In France the question of race suicide is most important. There can be no reliable information on the subject when cases of abortion are not reported. The second is the protection of the physician. The physician is often called to attend a married woman in an abortion, which, so far as he knows, is accidental. It sometimes happens that the abortion is self-induced, or brought on by a professional abortionist. In that case, should the woman die, the physician is placed in a rather awkward position. If he is called to treat a fatal case of peritonitis and it is discovered afterward that the woman had an abortion he will have great difficulty in clearing himself. As a matter of fact, many physicians do report cases of abortion. Some report to the coroner, others to the district attorney. Some report all cases, whether they suspect anything criminal or not, in order that they shall be protected should a fatal termination occur; some report only when they suspect that a crime has been committed; some report only when they think the patient is going to die. The question that I would like answered is: Who should be notified when a physician desires to report a case of abortion? In my opinion, it is the registrar, or health officer, rather than the coroner, or district attorney. The third point was brought out by one of the speakers, namely, the education of the people. People have an idea that a fetus is not a living person and does not amount to anything; that to bring on an abortion is of no consequence at all. If every product of conception were regarded the same, if all women were made to realize that the passage of a product of conception through the birth canal is a birth, and the death of the fetus is a death, to be reported just the same as ordinary births and deaths, they would begin to realize that there is something serious in bringing on abortions, and no doubt the morals and the health and the welfare of the community would be advanced.

THE DEAF CHILD AND THE PHYSICIAN *

JOHN DUTTON WRIGHT

NEW YORK CITY.

I wish to express my appreciation of the breadth of view shown by your Section in placing this paper on its program. It is an excellent example of the broad-minded attitude of your profession toward your work, showing that you feel that your responsibility to your patients does not end at the office door.

During the twenty-one years that I have been engaged in the education of the deaf by the oral system I have always found physicians much interested in the subject. Every child whose hearing is defective is first taken to the family physician, who is usually a general practitioner, and in most cases sooner or later he advises that a specialist be consulted. On these two men rests in large measure the responsibility for the highest welfare of the child. In some cases the best efforts of the best men can not restore to the child a sufficient degree of hearing to enable it to understand ordinary conversation under everyday conditions, and the parents, in their inexperience, naturally look to the intelligent and experienced physician to show them what course must then be followed.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

It is at this point, while medical science continues to do all in its power for the child, that the educator steps in and helps in some measure to overcome the handicap by training the brain, the eye and the imperfect sense of hearing to share in common the increased burden.

We have to deal with three classes of deaf children: (1) those totally deaf, either congenitally or in early infancy, (2) those rendered deaf by accident or illness after speech and some language have been acquired, (3) those partially deaf, but with enough hearing to acquire some speech and language through shouting near the ear.

The first class, those totally deaf from birth or early infancy, must be taught language and speech without the aid of the ear. The other two classes must have their speech preserved and improved by careful instruction. All three classes must be educated and taught to understand the speech of others, either by the sense of sight alone or with the combined assistance of eye and ear.

This is neither the time nor the place to enter into any discussion of the general problems of the education of the deaf. They differ from the ordinary problems of education because the ear is not only the teacher of speech, but it is also the channel through which we get much of our language and the mental development which can alone be attained through language. The general public does not appreciate the greatness of the task of teaching language to a deaf child and presenting to him even a portion of the vast body of facts and ideas that he would get almost without effort if he could hear.

In their effort to express themselves the children often say amusing things. One of my little girls when asked what language is spoken in Spain replied promptly, "spinach."

A little tot in the kindergarten whose vocabulary was as yet very limited returned from the window, whither she had been sent for observation, and reported that she saw "a man broke." Not such an unusual thing, of course, yet the teacher was puzzled. On looking for herself she saw on the other side of the street a man with a wooden leg.

A boy describing a most exciting woodchuck quest, wrote, "The boy holed the ground with his dig, and the dog hurrahed with his wag."

Another chap wrote in his morning journal, "The wind is very blew and I am a little shiver."

The deaf child of 5 starts behind the hearing child of 2. He goes forward slowly and laboriously, but if taught by modern scientific methods, by the age of 15 or 16 has very nearly overtaken his hearing brother, and, besides, has acquired speech, lip-reading and language, a tremendous task in itself.

You are all aware that a child possessing normal speech, even up to 8 years of age, will lose that speech and become a deafmute if hearing is lost and he is not promptly given special attention for the purpose of preserving his speech. It is astonishing how quickly articulation will begin to deteriorate when hearing is lost, unless the greatest care is exercised. In cases, therefore, in which deafness is brought on by illness or accident, after speech and language have been acquired, the physician should insist on special supervision of the speech by a trained instructor even while medical treatment is still going on. I have found that this necessity for prompt action is not always appreciated by physicians.

A physician has few tasks less pleasant than that of telling the parents that their child will probably always be deaf, and he may well be excused for softening the facts so far as possible. Yet he owes it to the child to make the father and mother intelligent on the subject, and should tell them what he himself knows so well, that without special care the child will either not learn to talk and to understand what others are saying, or the speech which it then has will grow gradually indistinct through lack of the guidance of the ear. And he should urge them to give the matter their immediate attention and put themselves in communication with some one experienced in such matters and be guided by their suggestions. If later the child's hearing should show improvement the attention which has been paid to its speech and education will have done no harm; on the contrary, it will have avoided the loss of precious time that can never be recovered. If, on the other hand, the child is never going to hear better, they will have taken the steps necessary to overcome that handicap so far as possible. Therefore, while they may expect the best, they have planned for all possible contingencies.

Parents frequently say to me by way of apology for not having dealt more wisely with their deaf children: "You see, it was all so new to us. We have never had a deaf child before and had no experience to guide us. We could only grope our way along and do the best we knew." Yet others had learned by bitter experience, and those coming after might easily have profited by their mistakes had the physician put them in communication with someone who knew. Physicians should therefore be able to suggest to parents some way in which they can inform themselves and obtain advice and guidance. Every state in the Union provides for the education of its deaf children to a greater or less extent. I will gladly send to any physician who will drop me a postal, or to any address requested, a list of available schools or teachers in the section of the country specified, and any other information that I think might be helpful.

Personally, I am not an advocate of beginning the actual teaching of speech to a totally deaf child as young as 2 or 3 years of age. Note that I say "totally deaf," for if there is some perception of sound it may be possible to train and develop that imperfect hearing so that it may greatly aid in the acquisition of speech, and this may be begun earlier than articulation teaching to a totally deaf child. It may be done by the mother or the father or older sister of a child if they will undertake it. But the training to understand spoken language by lip reading can not be begun too early in any case, and therefore it is desirable that the parents should know at the earliest possible moment if a child has imperfect hearing. All physicians have undoubtedly seen children in whom deafness was undiscovered or neglected for a surprising length of time, and, on the other hand, they also know the difficulties attending an accurate determination of the degree of hearing of a very young child. But the child should be placed under trained and experienced instruction not later than 6 years of age, and, if physically strong and well developed, it is better to begin at 4½ or 5.

That there is a language learning period is well known to every educator. Centuries of inheritance have rendered the years from 2 to 12 the principal language learning time for the child. The deaf child that has not acquired much language by 12 years of age is doomed to a bitter and discouraging struggle, and it is cruel to let anything interfere with the greatest possible progress in the first ten years of the child's life.

There is no reason for bringing into this paper anything of a controversial nature, but I may say that the educators of the deaf are still somewhat divided, and that while the lines of separation are by no means so sharp as they were, there are still oralists and manualists. Those who employ the manual alphabet and gestural signs in the educational process, and those who exclude all forms of communication not employed by hearing people. I am a pure oralist. My twenty odd years of labor in the work with the deaf have left me still of the opinion that they can be given as good an education by purely oral means as by manual means and, in addition, a priceless boon in the ability to speak and understand the speech of others.

The first school for the deaf in this country was founded in 1817. It was a manual school and the pupils were deaf and dumb. For fifty years all pupils in the schools of this country were taught wholly by signs, manual alphabet and writing. It is for this reason that the terms "deaf and dumb" and "deaf-mute" are so deeply imbedded in the public mind that many people even to-day do not realize that dumbness is not necessarily an accompaniment of deafness. The first school in the United States where the pupils were taught exclusively by means of speech and writing, without signs or the manual alphabet, was established in 1867. Twenty-six years later, in 1893, 25 per cent. of the 8,000 pupils in the schools for the deaf in the United States were taught by the pure oral method. In 1908, fifteen years later, there were 12,000 pupils in school and 56.5 per cent. were taught without the use of signs or the manual alphabet. At the same rate of progress another generation should see the practical disappearance of manual methods from the schoolroom.

It is more expensive to educate a deaf child without recourse to manual methods. It requires a larger proportion of teachers to pupils and a greater degree of training and experience. But it is worth while, and the people of the country are rapidly coming to know it and to decline to accept anything but the best.

Up to fifteen years ago if there came to a family of wealth and refinement a deaf child there were but two alternatives for its education. Either a governess or tutor must be provided at home and the child taught alone, or it must be sent to one of the institutions provided by the states. The same fine private schools that were open to the deaf child's brothers and sisters were closed to him or to her. His or her education had to be obtained under less favorable and agreeable conditions. I was then a teacher in a large public institution for the deaf, having previously served my apprenticeship as a tutor of deaf boys in their homes. It seemed to me that there should be provided, for those deaf children whose means enabled them to avail themselves of the best, as fine a private school as the great city of New York could offer to a pupil with unimpaired hearing. The expense of conducting such a school would necessarily be much greater *per capita* than that of an ordinary school, for a staff of ten or a dozen trained teachers would be necessary for twenty or twenty-five pupils. All the wiseacres shook their heads and said I should be very foolish to undertake such an enterprise. But with the courage of youth I ventured to disregard their advice, and have never had reason to regret my rashness. My most famous pupil, and one of the most interesting, was the most heavily handicapped, for she was the only pupil I have ever had, or probably ever will have, who is both blind and deaf. Yet Helen Keller went through the regular course at Harvard, obtaining her degree, and hers is a household name to-day. Her success has led to the picking up of one more loose thread in our civilization, and to-day there are many deaf blind pupils under instruction in various parts of the country.

Physicians can, if they will, exercise great influence in their own localities. Let me mention two or three points on which there is no time to dwell, but to which attention should be called.

1. The education of the deaf is not a charity any more than the education of your own sons and daughters.

2. All education, and especially the education of the deaf, should be wholly and forever divorced from politics. In too many instances the guidance of institutions for the deaf is entrusted to men of political rather than educational efficiency, and changes in control are made not for the purpose of bettering the school, but for purely political reasons. This is outrageous cruelty to the helpless and dependent child, who innocently suffers for the pride or purse of the politician.

3. The great body of deaf children are bright and normal mentally, and it is unjust to compel the state institutions to include the few abnormal and feeble-minded among the bright ones simply because they are deaf. The feeble-minded deaf should be segregated and taught in schools by themselves as are the hearing feeble-minded.

4. The physician should lend his intelligent aid in placing the deaf child in the school best adapted to his needs.

1 Mount Morris Park, West.

ABSTRACT OF DISCUSSION

Dr. G. Hudson Makuen, Philadelphia: I regret that Mr. Wright's paper has not been more generally heard by members of the section. He has told us things that every otologist ought to know, and I fancy we all do or did know the greater part of it. We know that we have to deal with two classes of deaf children, the congenitally deaf and those who have acquired deafness, and that if the deafness is acquired before the seventh or eighth year, the speech of the child is liable to deterioration. We know also that we have among our little patients those who are only partially deaf and if left to themselves they are but a little better off than totally deaf children, so far as speech is concerned. We know that the modern tendency is distinctly away from the manual and toward the oral method of speech for deaf children. We know that there are public state institutions in which the various methods are taught in various ways, and that there are private institutions such as the one which Mr. Wright has founded.

We know all these things, but what we do not know and what we would like to know is just what these methods are, and how they are applied in the education of the deaf. Now I know nothing of the school over which Mr. Wright presides, and therefore what I shall say does not apply to it, but it has been my fortune to see a great many pupils both during and after their course in other institutions, and I must say that I rarely see one whose speech quite comes up to the standard which I would set for the deaf. I have therefore come to the conclusion that there must be something wrong with their methods. From what I have heard, Mr. Wright's must be in all respects a model school for the deaf, and therefore I am the more disappointed because he did not give us an opportunity to-day to discuss the methods which he employs. I am aware that the oral method of teaching deaf children is a comparatively new thing, and for this reason, I suppose, teachers have not acquired the necessary skill to enable them to accomplish the best results. Too much time, it seems to me, has been given to the teaching of the understanding of language through the visual organs, and not enough to its natural expression through the vocal organs, and too many children who are only partially deaf, are placed in the first or totally deaf class, and receive the same kind of treatment, no effort at all being made either to develop their hearing or to make use of the little hearing they have in the development of speech. It is quite as important, I think, to develop good voice, natural intonations and inflections, in the deaf, as to teach them to understand the language of others, and the teaching of these intonations and inflections, by the way, is a very effective means of helping them to develop an understanding of the speech and language of others.

The other day a small boy was brought to me in consultation who had been for four years in one of our largest institutions for the deaf, and his speech was almost entirely unintelligible, notwithstanding the fact that he had a very considerable amount of hearing power, for the development of which, by the way, absolutely nothing was being done, nor indeed was any use being made of his hearing power in the development of speech.

Mr. Wright says that the feeble-minded deaf should be segregated. I would say that the totally deaf should likewise be segregated, and the hard of hearing, and partially deaf, should be taught to hear as well as to speak, after the manner of Urbantschitsch, of Vienna, and myself of Philadelphia. Their speech should be developed as much as possible through the hearing. I have seen better results obtained with dispensary cases in my own clinic than with the pupils of the large institutions. Moreover, a large proportion of these deaf children are found in poor families who can not pay for any kind of instruction or treatment, and here is an opportunity for a splendid charity. The whole work, in my opinion, should be in the hands of the physician with whom teachers should be directly associated. The teacher, it is true, can do much for these deaf children, but the physician can do quite as much and often more for all those who are only partially deaf and who are acquiring deafness. The teacher can do more than the physician for those who are totally and irretrievably deaf, but they constitute, in my experience, only a small percentage of the entire number coming under our attention and care.

The progressive otologist and laryngologist, therefore, should make himself familiar with the methods of teaching deaf children, and he should have associated with him in his office a teacher to assist him in the practical application of these methods. The physician can not do it of himself, nor indeed can the teacher, but physician and teacher should work in immediate conjunction if the best results are to be obtained.

Dr. Dennis J. McDonald, New York: Two years ago I took up this work with the city authorities of New York, but, strange to say, large cities like New York were the last to take up improvements. I managed to get an appropriation of $50,000 last year for the cases referred to by Dr. Makuen. I have visited many institutions in this country to observe the methods of teaching and could not help but be impressed with the sacrifices of these educators.

I disagree with Dr. Makuen in the statement that physicians have the time to go into this work. The state should be made to understand that these children are as much entitled to education as any others. It behooves otologists to take a special interest in the advancement of this work. In every great school there should be an otologist who should determine the condition of these children on admission and who could examine and report every six months on the condition of these children in regard to the perception of language. If the members of this Section would enter into the spirit of the matter before this time next year great advances in the work would have been made.

Dr. Maury M. Stapler, Macon, Ga.: Deafness in some of these children is caused from the fact that the Eustachian tubes are closed and the air pressure forces the ossicular chain out of position; it is held so until the stapedius muscle is overcome. There is no method of pulling these bones out from the oval window. I have opened up the tubes, applied the suction apparatus and obtained good results in some of these cases. In five minutes some of the children could get up and repeat words. I think that the otologists should take up this work.

Dr. J. Holinger, Chicago: In 1897 I examined the ears of the 504 deaf children in an institution at Jacksonville, Ill. The findings were extremely varied and interesting, and if for no other reason than this, I think attention should be drawn to the fact that a vast amount of knowledge can be acquired in examining the inmates of an institution for the deaf. The results of my examination turned out to be a perfect pathologic museum of all kinds of otologic conditions imaginable. From one ear, for example, a large cholesteatomatous mass was removed containing a sequestrum in the center, leaving a perfectly smooth cavity of the size of a walnut, consisting of external meatus, middle-ear, antrum, mastoid cells and the labyrinth which was lost, together with the other bony parts. Any number of other equally interesting findings might be described. We should try whenever we have the opportunity to make such examinations. Then we will be led to the fundamental work of Bezold, who shows that children who hear tuning forks from b′ to g″ can be taught to use their hearing for talking. It is surprising that these tests are not made more regularly in the institutions.

Mr. John D. Wright, New York: As to Dr. Makuen's regret that I did not take up the methods of teaching, I would say that I shall be glad at any time to read a paper before this Section on that subject. The failure that Dr. Makuen has spoken of in the large institutions for the deaf to develop the imperfect hearing of the pupils is due to lack of sufficient teachers. This Section is influential and should take up this matter. The education of deaf children is not a charity, but is their right just as much as the education of your child is a right. And do not call the schools for the deaf asylums; they are no more asylums than are the public schools; they are schools for the deaf.

AN IMPROVED METHOD OF APPLYING THE PLASTER JACKET

K. D. PANTON, M.B., M.R.C.S. (Eng.), L.R.C.P. (Lond.).
VANCOUVER, B. C.

The following method of applying the plaster jacket in cases of Pott's disease was developed in the emergencies of practice and proved so simple and satisfactory that I have since used it in preference to the older methods:

The plaster jacket must be so applied that it will prevent any movement of the bones in the diseased part of the spine and will also hold the spine in a hyperextended position. The hyperextension transfers the superimposed weight of the head and shoulders from the diseased bodies of the affected vertebræ to the articular processes. In this way all possible movement and pressure are taken from the diseased parts of the vertebræ and resolution is promoted. It is a fallacy to suppose that the jacket can support the weight of that part of the body lying above the diseased area by being built high in the axillæ and holding up the shoulders. Such a cast would cause unbearable pressure and pressure sores in the axillæ. All jackets must fit snugly and have a good grip on the pelvis.

There are various satisfactory methods of applying plaster jackets to children, but to the adult the application is more difficult. The usual method of partial suspension, with the Sayre apparatus, is most uncomfortable for the patient, and he has sometimes to be taken down before the plaster is well set, which results in a poor jacket. It is also difficult for the operator to apply the bandages snugly, for he has to work fast and the patient's body sways more or less. In the following method the patient lies comfortably on his back, his body is quite steady, and the operator can take all the time necessary to apply the bandages with accuracy.

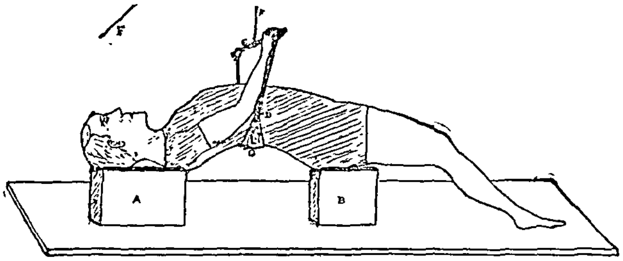
Briefly, the patient lies in the dorsal position, raised about a foot above the operating table. His hips and neck rest on suitable supports and his back is supported on a canvas sling which goes around his back under the kyphosis. The ends of the sling are attached to a spreader. The spreader has a rope and pulley attachment fastened to the ceiling by which it can be raised or lowered. With this apparatus the sling is drawn upward until the back of the patient is sufficiently hyperextended, and the plaster bandages are then applied. The central part of the sling is included in the jacket, while the ends emerge at each side. Although holes are necessarily left at these points, they are small and in no way affect the efficiency of the cast. When the plaster is well set, the ends of the sling are cut across at their points of exit from the mold and the patient is transferred to bed. The central part of the sling remains permanently in the jacket.

The sling is made of stout canvas about 5 feet long, 5 inches wide at the center and narrower toward the ends where it will penetrate the cast. After the patient is in position on the sling, the latter can be made still smaller at these points by tying pieces of string tight around it. The padding of the sling must be very carefully done, for if it does not fit the kyphosis accurately a pressure sore may occur. Horse-collar felt or silence cloth should be used and several pieces sewed to the sling so that they will form two ridges with shelving edges that will lie along each side of the kyphosis and approach the middle line above and below it. Care should be taken to be sure that there is equal pressure all around the kyphosis, that its tip does not project through the padding and press against the sling, and that there are no abrupt edges of felt against the skin.

The spreader, a stout stick about 2 feet long, when in position, lies across the body of the patient. To its ends are attached the ends of the sling and to its center is attached a rope with a pulley attachment in the ceiling by which it can be raised or lowered. Two boxes, a foot high and padded on top, make good supports. The upper one supports the head, neck and tips of the shoulders, while the lower one lies under the lower part of the buttocks. The heels rest on the table. If the jacket is to be made unusually high or low, of course, special supports will be needed.

As for the actual operation, the stockinette shirt is put on the patient, the sling and spreader are adjusted and he is raised onto the supports. The pads are next sewed to the shirt. Then the sling is drawn up further until the back is well hyperextended. It is surprising how secure the patient will feel. The sling grips the back and sides of his body and holds him firm. After making sure that the sling is in exact position and the body is not twisted in any way, the plaster bandages are applied. This is done without hurry; they are put around the body in layers, going from bottom to top. An assistant follows the operator, rubbing the bandages well together and adding more water or plaster as may be needed. I prefer home-made bandages, 5 inches wide and 6 yards long. No salt or alum is needed in the water, as the plaster sets better without any such addition. When the bandages are all on, hollows are cut to allow of movements of the limbs, and, after the plaster is well set, the sling is cut across on each side where it emerges from the cast and the patient is transferred to bed.

For the advantages of this method it may be said that the patient lies in an easy and firm position and the operator can take all the time necessary to do his task thoroughly and make a snug cast. The back can be hyperextended as much as is necessary to be sure that the body weight will be transferred from the diseased bodies of the vertebræ to their articular processes. The body weight is transferred by the whole breadth of the back to the sling, and there is no undue pressure on the kyphosis. There is no hard breathing of the patient with movement of the chest and shoulders, which sometimes occurs when the suspension apparatus is used, causing the upper part of the cast to be loose. The patient can lie on the sling for hours if necessary until the plaster is set. The apparatus can be made anywhere out of common materials.



Patient in position on the sling; a, neck support; b, pelvic support; c, sling going around back under the kyphosis; d, string tied around the sling at the point where it will go through the cast; e, spreader, 2 feet long; f, rope which goes through a pulley in the ceiling; g, site of kyphosis.

261 Hastings Street, East.

REPORT OF FIFTEEN CASES OF PELLAGRA

EDWARD B. BAILEY, M.D.
DEMOPOLIS, ALA.

The following observations have been made on fifteen cases of pellagra which have occurred in my practice during the last eighteen months.

As to etiology, all the patients gave the history of having eaten corn-bread. The usual symptoms of pellagra were exhibited in most instances, so that a mere summary of the observations will be given here. The *previous health* had been good in most cases, except that there was a history of alcoholism in two, and one patient had been confined to bed for four years with multiple spinal sclerosis. In some cases I saw the patient in a second attack. Of *the fifteen patients,* twelve were females. The ages varied from 7 to 60 years. Most were adults of middle age. There was fever in most cases ranging from 99 to 101 F.; in one case the temperature reached 103. The pulse varied from 100 to 130. Marked weakness characterized the general condition in most of the cases. The mind was somewhat affected in three cases. There was diarrhea in fourteen cases, stomatitis in eleven and an eruption in fourteen. The eruption was marked on the legs in one case and did not appear in one case until other symptoms were pronounced. There was vaginitis in three cases, accompanied by edema of the vulva in one.

There were ten deaths, three apparent recoveries, and two patients are at present improved.

Arsenic in the form of Fowler's solution or of atoxyl was given in five cases, but in several it was begun only a few days before death, so that no conclusion as to its value can well be drawn. Transfusion of blood from a recovered pellagrin was performed in one case, but was unsuccessful, death following in less than five hours.

APPARATUS FOR PROCTOCLYSIS AT AN EVEN TEMPERATURE

R. M. HARBIN, M. D.

ROME, GA.

There are certain requirements in the use of salt water by the rectum in peritonitis that must be met: (1) an even temperature for the solution; (2) slow instillation; (3) provision for an escape of rectal gases and the regurgitant flow. Numerous forms of apparatus have been devised, but because of the expense and difficulty of obtaining them they have not come into general use. The apparatus here described was improvised and put into operation in thirty minutes. The ordinary bottle, made on the principle of vacuum non-conductor, found in nearly every drug store, will keep the solution at even temperature. A perforated rubber cork, glass tubes, and a discarded stomach-douche with a rubber funnel are all that are needed in addition.

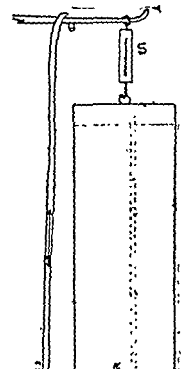


Diagram of apparatus for the instillation of physiologic salt solution into the rectum at an even temperature; S, scales; T, tube thermometer; P, joint; F, soft rubber funnel.

The introduction of the solution, drop by drop, is accomplished by making a joint at P with a small glass dropper or pipette. A tube thermometer may be inserted at T. The ventilator-pipe will dispose of the rectal gases without contaminating the reservoir; it applies the same principle as the ventilating-pipes of plumbing. The end of this ventilator-pipe must be slightly higher than the reservoir. The small caliber of the joint P seems to prevent overdistention of the rectum; but if this should occur the escape-pipe could be made to empty into a basin. Ordinarily there is a slightly intermittent flow, but as intrarectal pressure increases it becomes more marked, and for that reason offers an advantage. Scales may be used and the nurse can chart by weight the solution consumed. This serves as an indicator for refilling. The loss of heat from the supply-tube is practically *nil*, but the latter may be kept covered with blankets. The apparatus should be inverted and disconnected at P for filling.

A patient with perforative appendicitis took, between 2 and 6 p. m., 8 pints of normal saline solution, then perhaps 1 or 2 pints escaped and the patient complained of fulness and slight dyspnea. A soapsuds enema was given and four hours later proctoclysis was resumed. During the next twelve hours 3½ pints were taken with no regurgitation. This made about 10 pints for twenty-four hours. The patient's improvement was such that the salt water was used intermittently.

In another case of acute appendicitis, without drainage, 8 pints were consumed during the first six hours with no return. These preliminary observations were made at my private hospital. The simplicity of this apparatus, the various methods of adjustment to meet certain indications and the ease with which it may be procured warrant further trial.

100 Third Avenue.

AN IMPROVED SALINE TRANSFUSION APPARATUS

JOHN M. GARRATT, M.D.

BUFFALO, N. Y.

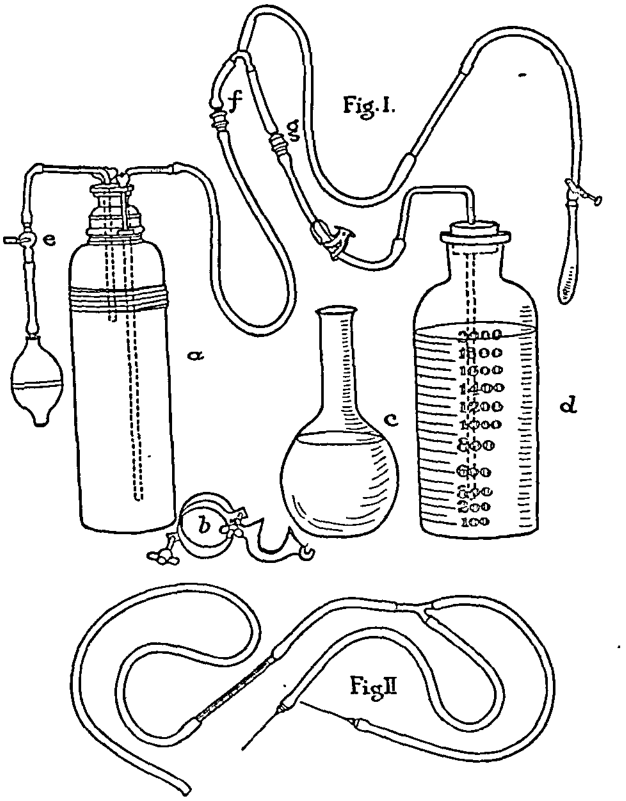
The introduction of saline solution subcutaneously, intravenously or per rectum, to support the circulation in shock and collapse, is markedly efficacious, and if properly given is perhaps the most valuable treatment for these conditions. Intra-abdominal transfusion of salt solutions into the peritoneal cavity, as advocated by Lawson Tait, is of undoubted value to combat shock following abdominal operations, as is also the employment of proctoclysis in the treatment of peritonitis and general toxemic conditions, as suggested by Dr. J. B. Murphy of Chicago.

Aside from the fact that the solution must be aseptic, the temperature of the solution as it enters the tissues is of the utmost importance. With the usual solution-containers—the fountain syringe, glass flask and glass pressure bottle—there is difficulty in maintaining an equable temperature, for they rapidly radiate heat, and usually there is considerable drop in the temperature of the fluid from the start to the finish of the treatment.

Since November of last year I have used as a container a vacuum bottle (originally suggested by myself) of sufficient capacity. The heat-retaining properties of this bottle makes it an ideal container. The apparatus here illustrated has been in use about a year and has proved very satisfactory.

The apparatus for tissue saline transfusion consists of parts adjusted as follows: The cork of the vacuum pressure bottle (a) is fitted with glass tubes, one long and one short. To the long end which dips into the solution is connected a rubber tube (Fig. 2), through which the fluid passes to the needle or needles inserted in the tissues. Near the needle is placed an infusion thermometer by which the temperature of the solution can be observed. The rubber tube attached to the short glass tube has at the end a pressure bulb. Near the pressure bulb a stop-cock is placed for the purpose of relieving the air-pressure on the solution when it is desired to check the flow of the fluid. A cork-holder (b) specially devised holds the cork in place. A small-necked flask (Koch form) of 950 c.c. capacity (c), in which the fluid is raised to the proper temperature, and a graduated bottle (d), capacity 2,000 c.c., in which is stored the saline solution when the apparatus is not in use, complete the outfit. These are placed in a box 8 by 10 by 14 inches. For emergency use are placed in the box also a glass jar containing a sterilized hypodermic syringe with needle and useful hypodermic tablets, and bottles containing adrenalin solution, spirits of ammonia, etc.

For rectal saline transfusion separate apparatus is desirable. The pressure bottle fittings are similar to the other apparatus, the difference being in the arrangement of the tubing attached to the long glass tube which is fitted with two valves, one (f) placed so as to prohibit the back flow of contaminated solution into the pressure bottle and to direct flatus gases to the bottle provided to receive them. The second valve (g) prevents fluid from the flatus bottle mixing with the clean solution. Figure 1 is self-explanatory.



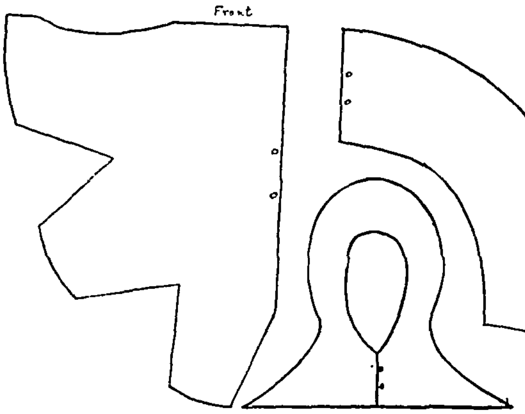
Figs. 1 and 2.—Apparatus for the introduction of saline solution at an equable temperature subcutaneously, intravenously, or per rectum.

Snap-Shot Radiograms.—One drawback to using Roentgen rays to photograph living subjects has been the time exposure required. To overcome this, says the *Scientific American*, a German inventor has devised an induction coil which produces one sudden and intense spark, making it possible to take an instantaneous radiogram. The effect is produced by using a fuse of small silver or copper wire in place of the interrupter in the primary circuit. This is melted when the proper intensity of the current is reached, thus suddenly breaking the circuit and producing an intense discharge. The exposure is from 1/50 to 1/120 of a second; and as it is a simple matter to replace the fuse, a large number of exposures can be made in the course of an hour.

A CAP FOR OUTDOOR SLEEPING

THOMPSON FRAZER, M.D.
ASHEVILLE, N. C.

When sleeping outdoors it is essential that the head and neck be protected from draughts; these are responsible for most of the colds caught by the inexperienced out-of-door sleeper. A knitted or woolen cap made according to the accompanying pattern will be found satisfactory. It covers the head completely except for a narrow oval for the face; in addition, it has a long tail which may be pushed under the pajama coat, thus affording protection to the neck.



Pattern for cap for outdoor sleeping, and diagram of finished cap; left, pattern of head-piece; right, pattern of collar; center, diagram.

TREATMENT FOR CHRONIC CONSTIPATION

GEORGE EDWARD BARNES, B.A., M.D.
HERKIMER, N. Y.

Although various methods of applying medication—diet, hydrotherapy, massage, etc.—in the treatment of chronic constipation have long been employed to the great benefit of multitudes of the afflicted, there has been lacking a treatment that is simple, convenient, effective and easy to be practiced by the patient. Of course, the treatment to be recommended to individuals must often vary. This is true, not only as regards their form of constipation, but also as regards all the abnormal conditions which accompany it and which should be given simultaneous attention. But it is of prime importance that all constipated individuals (especially children) should daily drink sufficient water and should, at the corresponding hour each day, visit the stool and there allow the slow, natural forces sufficient time to act, for in this way there is often established a habit of daily evacuation which is curative.

In cases in which a moderate amount of straining in a stooping posture is not effective the inadequate powers may often be successfully reinforced by a new application of massage. While still seated, the patient places the palmar surface of the fingers of his right hand over the upper part of the descending colon and, making slight pressure, massages with a spiral, descending movement that tube and part of the sigmoid flexure. The finger should preferably be cold. If they are warm they may be cooled in cold water or, in their stead, a suitable cold object, such as a small, smooth glass paperweight, may be used. The cold massage applied at this time initiates a peristalsis which propels the fecal contents downward forcibly into the ampulla recti and thus sets up the normal reflex of defecation. In practice the bowel may be massaged as described three or four times and then an effort at expulsion in stooping posture may be made, and these procedures should be alternately repeated, increasing gradually the pressure of the massage, until there is a successful issue. In order to increase abdominal pressure while straining, the folded fist may be placed two to four inches above the left Poupart's ligament and held there firmly while the soft abdomen above the fist makes gentle pressure on it as the body flexes forward. There is little danger of massaging too hard, but, of course, too strong pressure should not be made, especially when the bowel is filled with hard feces. But such a condition will not occur with daily evacuations. The pressure should be graded somewhat according to the thickness of the abdominal parietes. Of course, this method may be used to supplement or to follow other methods.

This cold massage treatment is not applicable to cases complicated with certain growths, hernias, pregnancy, or certain acute and chronic inflammations of the abdomen and pelvis. In cases of visceral ptosis it is often not advisable, especially in prolapse or displacement of the female generative organs, although it may be used in moderate gastroenteroptosis, provided the left kidney is not descended.

The value of this method is due to the fact that not only is a daily movement produced, but also the whole descending colon and rectum are assisted and trained to empty themselves more or less completely every day, thus to save the patient from the greatest chances of incurring autointoxication and appendicitis.

Therapeutics

TUBERCULOSIS OF THE JOINTS

During the last twenty-five years it has been definitely established that a large proportion of chronic suppurative inflammations of joints are tuberculous in character. These tuberculous joints are sufficiently frequent for every general practitioner, at least occasionally, to have a patient with this disease, and he should be prepared to apply correct treatment, or at least to know what is correct.

Certain general principles of treatment are applicable to all cases:

First.—The patient should be surrounded with the best possible hygienic conditions. He should have abundance of fresh air, preferably out of doors, for a large part of, or the entire day. He should be liberally provided with nourishing and easily digested food, including milk and eggs, to the extent of his tolerance for them. He should be warmly clothed in order to prevent internal congestions due to cooling of the surface of the body. Massage should be employed to prevent atrophy of the muscles while he is at rest.

Second.—The affected joint should be placed at rest, or, as many say, immobilized. This rest or immobilization may be secured in a variety of ways, depending on the particular joint affected and the stage of the disease. At the beginning of the treatment it is generally wise to confine the patient to bed and to employ such immobilization and extension as is practicable. In the case of the hip-joint this may be secured by Buck's extension method and a long side splint. After a few weeks it will generally be found that the inflammation in the joint has become less active and that the general constitutional symptoms have improved. Then it is desirable, in most cases, to take the patient out of bed and to permit him to move about. But the immobilization must be maintained by suitable apparatus. Steel splints or braces, carefully padded, are generally preferred to those made of wood, leather, or plaster, because slender rods of this material possess great strength and practical inflexibility and allow of frequent inspection of the part under treatment and readjustment of the apparatus.

Most American surgeons believe that, when practicable, extension should be combined with immobilization, but some British surgeons believe that this is not so absolutely indispensable that other desirable factors of the treatment should be neglected, when it is impracticable to make use of all at the same time. Certainly immobilization is more important than extension when both cannot be secured simultaneously. In advanced cases, especially when the vertebræ are affected, extension is sometimes injurious and should not be attempted.

The various phases of the subject were exhaustively discussed before the British Medical Association, a report of which appeared in the *British Medical Journal*, Oct. 2, 1909.

The determination of the opsonic index and inoculation with tuberculin were spoken of by Mr. Maynard Smith, of London, who reported 34 patients treated in the inoculation department of St. Mary's Hospital, of which 21 were cured; 9 were improving and still under treatment; 2 had been under treatment for only 2 or 3 months, and 2 failed to show any improvement after six and ten months' treatment.

After a tuberculous abscess has formed, the question of opening it must be considered. Concerning these Mr. Robert Jones, of Liverpool (*British Medical Journal*, Oct. 2, 1909), said: "Experience has convinced me of the value of leaving certain types of tuberculous collections alone as long as possible. I disregard them if they give rise to no symptoms. They are only serious or urgent if they are infected from within or without. It is a mistake to attach the clinical importance to a tuberculous abscess that we do to a collection of pus. The tubercle bacillus we know is not pyogenic. When true suppuration occurs, it is due to a secondary infection. Efficient fixation undoubtedly lessens the liability to abscess formation and also facilitates their disappearance. In a well-immobilized spine a large proportion of these abscesses disappear. Writers who do not observe this obviously never give time for it to occur. In the hip-joint they are especially apt to become nomadic, changing their residence from within the joint to residence without. They become extra-articular in the sense of having no connection with the joint. Often I have noticed collections having appeared from the joint travel down the thigh, become isolated, and then gradually dwindle away. The process of absorption is not characterized by any clinical manifestation. I refuse to open tuberculous abscesses early, not because I dislike a radical operation, but because an operation is necessarily incomplete and ineffective if it cannot remove the disease of which the abscess is but a symptom. If opening the abscess meant the eradication of the disease, clearly the problem would be solved.

"In many cases, however, the abscess is not absorbed, but travels toward the skin. An abscess which forms early in tuberculous disease and is evacuated is, in my opinion, a more serious affair than the abscess treated in this later stage. Simple aspiration of a distended sac will prove of value, and this may have to be repeated frequently. Usually, however, I prefer allowing the abscess to invade the surface, when I make a small puncture ½ inch in length (or less), using the strictest aseptic precautions, scrupulously avoiding the Volkmann's spoon or irrigator, for I do nothing to interfere with the thick sac wall, which provides so admirable a barrier against infection. If these abscesses be attacked in this way, the terrors of infection are assuredly much diminished; for the delay of many months in opening the abscess has given the joint time to make progress, the supply of débris is shut off, and the long, exhaustive discharge which follows early incision is curtailed. I have no conviction more settled in my mind than that of the value of a conservative attitude toward tuberculous abscesses. When we remember that hospital surgeons, with all the facilities for the practice of a rigid asepsis, see only an infinitesimal proportion of these cases, and that the overwhelming number are in the hands of practitioners in slums and country places, handicapped by their environment, totally unable to insist on surgical cleanliness, the policy I advocate seems to me of great importance. My experience warrants me in saying that numbers of children die in all parts of England and Wales because we do not realize the many responsibilities involved in the routine opening of tuberculous abscesses.

"If, however, with the presence of fluid, discomfort, pain, and temperature are present, or if the patient rapidly or steadily declines in condition, then the abscess may be suspected and attacked by good incision, bone searched for, and antiseptic irrigations adopted. Here there will be found a mixed infection, and surgical interference is urgent and most effective where most radical. Again, for geographical reasons, a retropharyngeal abscess demands immediate incision, preferably behind the sternomastoid, and in those rare instances of collections in the posterior mediastinum where one finds spasmodic attacks of dyspnea, evacuation should be immediate by costotransversectomy over the affected articulation."

With regard to resection of tuberculous joints the teachings of Jones show evidence of wise conservatism based on wide experience. He points out that tuberculosis produces very different effects in children from those observed in adults. In the child, when judiciously treated, its progress is benign. In the adult, on the other hand, it is more intractable and more likely to result disastrously.

In children an early excision is usually unwise, being followed by great deformity from interference with the growth of the limb. A late excision is usually useless, an amputation being generally necessary.

In adults general dissemination is more likely to occur, and consequently an early operation is more urgently demanded. This results in earlier and non-complete fixation of the joint, which is the object which Nature strives to attain in cases not subjected to operation.

In advanced cases of tuberculosis of the joints discharging sinuses are often present, and these frequently persist for years.

Emil G. Beck, Chicago (*British Medical Journal,* Oct. 2, 1909), has proposed to treat these sinuses by injections of a paste made by mixing, while boiling, bismuth subnitrate and petroleum, the resulting paste containing 33.3 per cent. of bismuth subnitrate. These injections, supplemented by Roentgen-ray examination, afford important aid in diagnosis. In many instances they also result in a cure of the sinus. Their use has sometimes been followed by untoward results, the paste blocking up the sinus and damming back the pus, so that septic infection has resulted. In some instances bismuth poisoning has occurred. It has happened that the bismuth injection in a thin-walled sinus near a joint has caused accumulation of pus near the joint, which has ruptured into and caused infection of the joint.

Bearing in mind the necessity for caution in order to avoid these unfortunate results, Baer, of Baltimore (*Bulletin Johns Hopkins Hospital,* October, 1909), believes that injection of Beck's bismuth paste will cause diminution of the discharge and healing of the sinus in many instances.

In connection with the evacuation of tuberculous abscesses, resection of the joints, and the treatment of tuberculous sinuses, mention must also be made of the use of iodoform.

Sir William Macewen, of Glasgow (*British Medical Journal,* Oct. 2, 1909), recommends the injection of sterilized iodoform emulsion, introduced into the center and immediate vicinity of the tuberculous part. This treatment is especially applicable while the disease is still discrete and confined to the epiphyses. It also acts favorably, but more slowly in the second stage, when the tubercles have become confluent, and caseation and liquefaction have occurred.

Macewen advises, after the radical removal of a local lesion, the application of a mixture of iodoform and boric acid, 1 to 4. He deems it important in this mixture for the iodoform to be in large crystals instead of in fine powder. The crystals are not readily absorbed, and are, therefore, not so likely to cause toxemia, and their local effect is continued for a longer time. The finely powdered iodoform, on the other hand, is rapidly absorbed, and may cause serious poisoning, while at the same time its local effects pass off quickly. The iodoform may also be injected into abscess cavities from which tuberculous fluid has been drawn off by an aspirator.

In speaking of para-articular tuberculosis, Mr. A. H. Tubby, of London (*British Medical Journal,* Oct. 2, 1909), recommends, after cutting down to the bone, and after evacuating the granulations and pus, and after thoroughly scraping the cavity, the application to all parts of the diseased region of either "camphorated naphthol, or, better still, a solution of chlorid of zinc of a strength of 10 per cent."

Finally arises the question as to what should be done with cured, but deformed, tuberculous joints. Robert Jones (*British Medical Journal,* Oct. 2, 1909) points out that "to break down such adhesions, or to endeavor to enforce 'passive movements,' would be a highly hazardous adventure." In otherwise suitable cases a careful experiment may be made by trying to increase the angle of the joint by five degrees by means of a splint worn for from ten to fourteen days. If this results in increased movement of the joint, a favorable prognosis may be given, and the treatment may be continued. If the joint remains stiff, perseverance may cause disaster.

Tuberculosis in Japan.—Kitasato contributes an article on this subject to the *Zeitschrift für Hygiene,* lxiii, 1909. The conditions in Japan are peculiarly interesting, as there are comparatively no cattle in Japan and consequently human tuberculosis is entirely independent of the bovine type. He examined the sputum of 152 consumptives continuously to detect the possible presence of bacilli of the bovine type but always with negative results, the human bacilli being found constantly in pure cultures. Statistics show that the disease is becoming more prevalent in Japan.

SATURDAY, DECEMBER 25, 1909

[The large amount of space occupied by the index this week makes it necessary to omit some departments and to curtail others.]

AMERICAN STANDARDS IN EDUCATION

In an address on "American Standards of Education," given before the American Association for the Advancement of Science,[1] Elmer Ellsworth Brown, United States Commissioner of Education, calls attention to the many efforts, mostly since 1900, made to standardize educational institutions in this country.

The fixing of standards is properly a state function; but no attempts were made by any state to standardize its educational institutions until 1892, when New York adopted a standard requiring that any institution to be ranked as a college (medical colleges seem to have been excepted) should have at least six professors giving their entire time to college and university work, that it should give a four-year course of studies of college grade, that it should require for admission four years of high-school work, and that it should have resources of at least $500,000, together with suitable provision for buildings, furniture, equipment and proper maintenance. In 1895 Pennsylvania adopted a standard requiring a four-year course and six regular professors devoting their entire time to teaching, but left the standards of admission and other matters to the judgment of a university council. In Pennsylvania likewise medical colleges seem to have been excepted from regulation. In 1893, in California, the state board of education was made responsible for the grading and classification of higher educational institutions. In 1907 the state educational board of Iowa was authorized to accept graduation from the courses in the state university and from other institutions of learning of equal rank in the state as evidence of fitness for a teacher's state certificate.

Besides the state efforts, various organizations have been working toward the standardizing of educational institutions. Among the organizations mentioned are the Association of American Universities, the College Entrance Examining Board, the Carnegie Foundation for the Advancement of Teaching, the National Conference Committee, representing several associations of colleges and secondary schools, the National Association of State Universities, and the Council on Medical Education of the American Medical Association. Mr. Brown names these organizations, not as a complete list, but to show how wide-spread is the effort to remove the stigma of reproach from American educational institutions. He then asks why legislatures should incorporate institutions, giving them the right to grant degrees, without making any provision for determining the meaning and worth of those degrees. He continues: "It is not merely an academic question. It is a moral question. False pretenses in the realm of education are a peculiarly flagrant form of fraud, for they cheat our American youth of their American right to a fair chance. They operate no less disastrously when . . . incompetent teachers . . . offer an inferior grade of instruction under the delusion that it is as good as the best. The well-meaning no less than the dishonest need some impartial test by which their educational offering may be proved, of what sort it is."

What Mr. Brown says regarding educational institutions in general applies with particular force to institutions professing to train practitioners in medicine, since the graduates of these institutions go forth with a much greater responsibility than the graduates of other schools. The public has the right to demand that medical colleges shall turn out as graduates only those who are well trained and capable of recognizing and combating disease.

THE CHURCHES AND TUBERCULOSIS

Certain metropolitan churches have organized what they call "tuberculosis classes." These consist of patients suffering from tuberculosis who, because of various conditions, cannot leave home, but who are taught how to live and disciplined in right living by regular attendance on what is called "class day" under the auspices of the church. Each week every patient brings for the inspection of the physician aiding in the work a book supplied for the purpose, in which he keeps an accurate and complete record of his daily habits, diet, weight, sleep and the amount of time he has passed in the open air. This enables the physician to suggest various improvements in the mode of living, to correct errors of diet and hygiene and to recognize early such special symptoms as may require treatment. The daily life of the patient, thus kept under a supervision such as is not possible when only a weekly or even more frequent visit to a dispensary is made, can be regulated almost as in a sanatorium.

A recent report of St. George's Church, New York City, shows how much can be accomplished during the course of a year for a small class of patients to whom individual attention is given. The results, considering that the cases cannot be so carefully selected as in sanatoriums, that the conditions are not so favorable and that there are many disadvantages, compare well with tuberculosis sanatorium statistics. Out of twenty patients, two were discharged as being "apparently cured"; four were "arrested," and five were "improved." More than half of the whole number of patients, though still living at home with their families, their ordinary lives being unchanged except by the advice of the physician, the influence of the example of others and the incentive gained from the movement, have been considerably improved in the course of a single year. The most important factors, of course, are the diet and the fresh air. These patients are taught and encouraged to live in the open as much as possible and to admit fresh air to their houses.

---

[1] Brown, E. E.: American Standards in Education and the World-Standard, Science, Oct. 1, 1909, xxx, 417.

The weight statistics are interesting. All except one who had been in the class for more than three months had gained in weight, the gain ranging from one to twenty pounds. The case of the one patient who lost in weight was an especially unfavorable one. Here are some definite results that show how much can be accomplished by instruction, example, discipline and charity for tuberculous patients even in city life. We say charity because some of the patients had to be helped to secure the proper nutrition. Here seems to be a good field for the churches. There can be no doubt of the benefit to be derived from the tuberculosis class movement.

THE INDEX

The index to the current volume of THE JOURNAL appears in this issue. The greatest care has been exercised to make it technically and mechanically perfect. Special effort has been made to bring titles under the fewest possible headings consistent with descriptive accuracy. And herein lies one of the difficulties in making a perfect index: authors frequently employ titles that are not sufficiently descriptive of the substance of their papers. The general plan of the index has not been changed, but it may facilitate its employment to restate it. The index is in three parts—the "General Index" is a complete index to all reading matter that has appeared in THE JOURNAL for the past six months, the "Index to Subjects" is an index of the articles that have appeared in the leading medical journals of the world during the same period, sufficiently complete and exhaustive for all ordinary purposes, and the "Index of Authors" contains the names of all authors whose articles are in the "Index of Subjects." Attention is again called to the "Guide to Current Medical Literature," a separate pamphlet in which is printed all the matter of the index together with the itemized lists of all articles that have appeared in medical periodicals. In this separate form it is extremely convenient and useful and avoids the necessity of handling loose copies or the bound volume. A better acquaintance with it would greatly extend its use.

Yellow Fever.—There has been no yellow fever in the United States during 1909 and a marked absence of it during the quarantine season of this year in Cuban, Mexican, West Indian, Central and South American ports, which is attributed to the greater attention being paid to sanitation.

Medical News

ALABAMA

County Society Meetings.—Shelby County Medical Society, at its annual meeting in Calera, December 14, elected Dr. John R. Pow, Maylene, president; Dr. Joel Chandler, Columbiana, vice-president; Dr. Eugene S. Miller, Columbiana, secretary; Dr. James F. Trucks, Helena, treasurer; Dr. Victor H. Williams, Calera, county health officer; and Dr. John I. Reid, Aldrich, censor.——Bessemer Medical Society, at its annual meeting, December 9, elected Dr. Thomas I. Conwell, president; Dr. Lucian A. Spencer, vice-president; and Dr. William Waldrop, secretary.——Colbert County Medical Society, at its annual meeting in Tuscumbia, December 7, elected the following officers: Dr. William H. Green, Tuscumbia, president; Dr. Walter J. Maxwell, Sheffield, vice-president, and Dr. Julius T. Haney, Tuscumbia, secretary-treasurer.——At the annual meeting of Limestone County Medical Society, held in Athens, Dr. Henry A. Darby, Athens, was elected president; Dr. E. Burke Hardin, Athens, vice-president; Dr. C. O. King, Athens, secretary-treasurer; Dr. Benton S. Pettus, Athens, county and city health officer; Dr. J. J. Pettus, health officer of Mooresville; and Dr. William E. Maples, health officer of Elkmont.——Jackson County Medical Society held its annual meeting at Scottsboro, December 10, and elected Dr. J. W. Boggess, president; Dr. William C. Maples, Scottsboro, vice-president; Dr. Edward Boyd, Scottsboro, secretary-treasurer, and county health officer; and Dr. S. H. Jones, censor.——At the annual meeting of Etowah County Medical Association, held in Gadsden, December 1, Dr. John P. Stewart, Attalla, was elected president; Dr. Herschel V. Baskin, Coats Bend, vice-president; Dr. William C. Williams, Gadsden, secretary; Dr. George L. Fawcett, Gadsden, treasurer; Dr. Hartford L. Ison, Gadsden, censor; Dr. Claude L. Murphree, Gadsden, city and county health officer (reelected); and Dr. James W. Cox, Gadsden, county physician, (reelected); Dr. James H. Wood, health officer of Attalla; Dr. William H. Acton, health officer of Alabama City, and Dr. John H. Ellison, health officer of Altoona.——The officers of the Morgan County Medical Society, elected at its annual meeting, December 2, are as follows: President, Dr. William L. Dinsmore, Decatur; vice-president, Dr. Felix B. Hunter, Falkville; secretary-treasurer, Dr. Joseph L. Gunter, New Decatur; censor, Dr. B. Walne Watson, New Decatur; county health officer, Dr. Frank P. Pettey, New Decatur; health officer of Decatur, Dr. William L. Dinsmore; of New Decatur, Dr. Michael W. Murray; of Hartsells, Dr. Hugh C. McRee; of Falkville, Dr. Felix B. Hunter; of Trinity, Dr. Frank Emens; of Austinville and Fairview, Dr. Roy M. Buchanan, New Decatur; of Flint, Dr. J. W. Crow; and of Somerville, Dr. P. W. Brindley; county jail physician, Dr. Henry C. Bracken, New Decatur; and physician to the poor house, Dr. P. W. Brindley.

COLORADO

Consumptive Hospital Report.—The tenth annual report of the Jewish National Hospital for Consumptives shows that 353 patients were treated last year, and that the expenses of the institution were $88,143; of this about one-eighth was used for the purpose of publicity.

El Paso County Physicians Elect.—At the annual meeting and banquet of the El Paso County Medical Society, held in Colorado Springs, December 8, Dr. Gerald B. Webb was elected president; Dr. Zenas H. McClanahan, vice-president; Dr. Lewis H. McKinnie, secretary; and Drs. Peter O. Hanford and Philip A. Loomis, delegates to the state society, all of Colorado Springs, and Dr. George B. Gilmore, treasurer, Colorado City.

ILLINOIS

Insane Endangered by Fire.—The north annex of the Jacksonville State Hospital was partially destroyed by fire December 21. The 200 insane women in that portion of the hospital were removed without casualty. The damage is estimated at $50,000.

Champaign County Physicians Meet.—Champaign County Medical Society, at its annual meeting, held December 9, in Champaign, elected the following officers: President, Dr. John Martin, Tolono; vice-president, Dr. Ellen Miner, Champaign; secretary-treasurer, Dr. Nellie M. Baker, Urbana; censors, Drs. Albert S. Wall and William L. Gray, Champaign, and James S. Mason, Urbana; delegate to the state medical society, Dr. William E. Schowengerdt, Champaign, and alternate, Dr. Clyde D. Gulick, Urbana.

Personal.—Dr. Rufus W. Gillette, Danville, is seriously ill in St. Elizabeth's Hospital, Danville.——Dr. Charles A. Griswold, Fulton, fell in his home, December 7, severely wrenching his right leg.——Dr. James H. Shepperd, Peoria, who has been ill with ptomaine poisoning, has recovered.——Dr. Edwin W. Reagan, Canton, has been elected president, and Dr. LeRoy R. Chapin, vice-president, of the trustees of the Murphy Hospital fund.——Dr. William K. Smith, LaHarpe, was operated on in the Macomb Hospital, December 5.

Chicago

Jonnesco in Chicago.—Dr. Thomas Jonnesco, of Bucharest, visited the city December 21 and 22, demonstrated his technic of spinal anesthesia at the Cook County Hospital, and also delivered an address on the same subject before the Chicago Medical Society.

College Election.—The Chicago Eye, Ear, Nose and Throat College held its annual meeting December 1, and reelected Drs. William A. Fisher, president; Dr. Adolphus G. Wippern, vice-president; Dr. John R. Hoffman, secretary, and Drs. Thomas Faith and Harry W. Woodruff, directors.

Juvenile Home Incorporated.—The Frances Juvenile Home Association was incorporated December 16, with the purpose of providing for, and giving medical treatment to children afflicted with offensive diseases, and of educating and making self-supporting, children entrusted to its care.

Heavy Cut in Health Appropriation.—The city comptroller has asked Dr. William A. Evans, health commissioner, to reduce the estimate of expenses of the health department from $607,000 for the year to $540,000. This, if done, will curtail the work of medical inspection, school nursing, vital statistics, and the activities of the sanitary bureau.

INDIANA

Personal.—Dr. Charles L. Thomas, Logansport, was seriously injured by the overturning of an automobile in Chicago December 6. His shoulder was dislocated, his jaw broken, and he suffered internal injuries.——Dr. Rufus F. Frost has been appointed secretary of the board of health of Huntington and Dr. Daniel Yingling a member of the board.——Dr. David Cohen, Jeffersonville, has resigned as township physician.——Dr. Charles B. Kern, Lafayette, has been reappointed physician of Tippecanoe county.——Dr. Winfield S. Faulds has been elected president, Dr. Harry F. Walsh secretary, and Drs. William P. Lane and I. L. Milstone, members of the Gary Board of Health.——Drs. Oliver P. Graham and Joseph Zuerner have been recommended for appointment as members of the Jeffersonville Board of Health.

Elections.—At the annual election of the Vigo County Medical Society, held in Terre Haute, December 7, the following officers were elected: Dr. J. Rudolph Yung, Terre Haute, president; Dr. Thomas C. Louks, Prairieton, vice-president; Dr. Charles N. Combs, Terre Haute, secretary-treasurer; Drs. Myron A. Boor and Malachi R. Combs, Terre Haute, delegates to the state association; Drs. Ernest W. Layman and J. Rudolph Yung, Terre Haute, alternates, and Dr. Bennet V. Caffee, Terre Haute, censor.——Ripley County Medical Association, at its annual meeting, elected Dr. James M. Pinkston, Holton, president; Dr. Reece C. Townsend, Osgood, vice-president; Dr. Bine Whitlach, Pierceville, secretary-treasurer; Dr. Theodore M. Brenton, Osgood, censor; Dr. John R. Pate, Milan, delegate to the state association; Dr. Edward D. Freeman, Osgood, alternate; Dr. E. D. Freeman, delegate to the district society; and Dr. George T. Beckett, Versailles, alternate.——At the annual meeting of Allen County Medical Society, December 7, the following officers were elected: Dr. Charles E. Barnett, president; Dr. Alfred L. D. Kane, vice-president; Dr. J. Clifford Wallace, secretary; Dr. William P. Whery, treasurer; Drs. Hermann A. Duemling, Samuel H. Havice and Edward J. McOscar, censors; Drs. Miles F. Porter and Charles R. Dancer, delegates to the state association, and Drs. Charles G. Beall and John H. Gilpin, alternates, all of Fort Wayne.——Floyd County Medical Society held its annual meeting December 3, at New Albany, and elected the following officers: President, Dr. Robert W. Harris; vice-president, Dr. Chester C. Funk; secretary, Dr. George E. Dash; censors, Drs. John Hazlewood, Henry B. Shacklett and William C. Winstandley, and delegate to the state medical association, Dr. Elihu P. Easley, all of New Albany.——Lake County Medical Society, at its annual meeting, held in Hammond, December 2, elected Dr. Eldridge M. Shanklin, Hammond, president; Dr. Theodore B. Templin, Gary, vice-president; Dr. Herman C. Groman, Hammond, secretary-treasurer; Dr. John E. Metcalf, Gary, censor, and Drs. William F. Howat and Herman C. Groman, Hammond, delegates to the state medical association.

IOWA

Personal.—Dr. Rosa M. Liebig has been reappointed overseer of the poor of Marshalltown.——Dr. Frederick A. Seemann is reported to be seriously ill at his home in Sioux City.——A fire, resulting from a defective flue, caused a damage of about $2,500 to the home of Dr. Alphonse L. Hageboeck, Davenport.——Dr. Elijah W. Jay, Marshalltown, underwent an operation for gall-stones in Augustana Hospital, Chicago, November 26, and is making a satisfactory recovery.——Dr. and Mrs. Thomas M. Wall, Osceola, have gone to the Isle of Pines for the winter.

Society Meetings.—The Cerro Gordo County Medical Society, at its annual meeting, held in Mason City, December 8, elected Dr. Francis E. McGlone, Mason City, president; Dr. Albin B. Phillips, Clear Lake, vice-president; Dr. Ida G. Rhoades, Mason City, secretary-treasurer. Dr. Walter L. Bierring of the State University held a clinic in the afternoon, and the annual banquet was held in the evening.——At the annual meeting of Johnson County Medical Society, held in Iowa City, December 1, Dr. Clarence E. Van Epps, Iowa City, was elected president; Dr. Calvin W. Harned, Iowa City, vice-president; Dr. Lawrence W. Littig, Iowa City, secretary-treasurer; Dr. Francis L. Love, Iowa City, censor; and Dr. Albertus J. Burge, Iowa City, delegate to the state society.——Iowa County Medical Society, at its annual meeting in Marengo, elected the following officers: President, Dr. Arnold C. Moon, Williamsburg; vice-president, Dr. A. F. Randolph; secretary-treasurer, Dr. Eric N. Brown, Marengo; delegate to the state society, Dr. Jasper L. Augustine, Ladora; censors, Drs. William H. Martindale, Marengo, Thomas J. Shuell, Parnell, and Edgar B. Henderson, Marengo.——Woodbury County Medical Society, at its annual meeting, held in Sioux City, elected the following officers: Dr. J. Herbert Darey, Sioux City, president; Dr. Ernest A. Jenkinson, vice-president; Dr. William J. Cremin, Sioux City, secretary; Dr. Roy M. Conmey, Sergeant Bluff, treasurer; and Drs. James F. Taylor, Salix, and Prince E. Sawyer, Sioux City, delegates to the state society.

KENTUCKY

New City Hospital.—Jefferson County Medical Society, at its last meeting, endorsed the plan of obtaining the passage of an act securing a bi-partisan hospital commission under which the new Louisville City Hospital could be erected by funds provided from a bond issue to be voted at the next general election. To create sentiment in favor of this act, a committee of five was appointed to wait on the commercial bodies, the mayor and the council.

Society Meeting.—At the annual meeting of the Franklin County Medical Society, held in Frankfort, Dec. 6, the society endorsed the bill regulating the sale of opium and its derivatives, and discussed the proposed ordinance regulating the sale of milk. The following officers were elected: President, Dr. Joseph L. Barr, Frankfort; vice-president, Dr. M. C. Darnell; secretary-treasurer, Dr. Urbane V. Williams, Frankfort, and delegate to the state society, Dr. Nevil M. Garrett, Frankfort.

Personal.—Dr. Charles Z. Aud, Cecilian, has been appointed a member of the State Board of Health, vice Dr. Joseph M. Mathews, Louisville, resigned.——Dr. Jefferson D. Pryor, Mayfield, was severely burned on the face in an explosion a few days ago.——Dr. William F. Scott, Somerset, is suffering from a broken nose, caused by a fall recently.——Dr. Robert L. Woodard, Hopkinsville, has been made medical director of the Indiana Industrial Life Insurance Company, Terre Haute.——Dr. James A. Averdick, Covington, is seriously ill with septicemia.——Dr. Thomas J. Glenn has been elected physician of Ludlow.

Milk Regulation.—At a conference between the State Board of Health, the representatives of the Louisville Health Department and the Indiana State Board of Health, it was decided that after the expiration of 90 days all milk being shipped into Louisville must come from herds that have been submitted to the tuberculin test and found free from tuberculosis. Under a regulation already in effect, the cattle shipped into the Bourbon Stock Yards for sale as dairy cattle must bear the stamp of the State Veterinarian as being free from tuberculosis. Much excellent work has been done in the county, but there still remains a large part of the dairy cattle to be tested. About 16 per cent. of those tested have reacted.

Inspection of Bakeries.—At a conference of the State Board of Health, representatives of the State Experiment Station at Lexington, and the city health department, a system of inspection and enforcement of the rules regarding the operation of bakeries was adopted. These regulations define the character of the building to be used as bakeries, lighting, plumbing, drainage, cleaning and care of walls and woodwork; specifies that bakerooms shall be used for that purpose only, not for sleeping, lounging or toilet rooms; spitting in workrooms is prohibited; cleanliness of employees, as to person and clothing, is enjoined; the health of the employees is regulated; the character of the water supply used is defined; well water cannot be used until a certificate of its analysis has been obtained from the State Experiment Station; wrapping of bread and bakery products in newspapers, and affixing tags to bread is prohibited; no flour, preserves, or jellies can be used until they conform to the regulation of the pure-food laws of the state, and the use of oleomargarine is prohibited.

MARYLAND

Personal.—Right Rev. Luther B. Wilson, M.D., will preside at the Baltimore Conference of the Methodist Episcopal Church next spring.——Dr. James H. Stauffer, Baltimore, is ill in Johns Hopkins Hospital, with leukemia.

Found Home for Widows and Orphans.—The Medical and Chirurgical Faculty of Maryland, which has had a fund since 1903 for the immediate relief of the widows and orphans of its deceased members, adopted plans, December 16, founding a home for widows and orphans, and appointed a board of managers to have charge of the home and administer its affairs. Subscriptions are already being received for this home and one gift of $1,000 has been pledged. The home will be located near Baltimore.

Special Legislation.—The Medical and Chirurgical Faculty of Maryland, at its meeting in Baltimore, December 16, considered certain important matters of legislation, and approved the proposed pure food and drug bill and the law to license and regulate midwives. The first of the bills follows closely the national pure food law, and provides for an appropriation of $10,000 a year to the State Board of Health for the enforcement of the law, and makes it mandatory on states attorneys to prosecute alleged violations. The second bill provides that a license be required from all midwives after July 1, 1910. The law is made not retroactive. In cases not normal, or in the case of inflammation of the eyes of the infant, the midwife must call in a regular practitioner.

Society Meeting.—At the annual meeting of the Baltimore City Medical Society, held Dec. 7, Dr. Harvey W. Cushing was elected president; Dr. Charles W. Mitchell, vice-president; Dr. W. Edward Magruder, secretary; Dr. William S. Gardner, treasurer; Dr. Charles E. Brack, censor (reelected); and members of the house of delegates, Drs. Samuel F. Earle, Jr., Herbert Harlan, William T. Lockwood, William S. Thayer, Edward L. Whitney, Richard H. Follis, Archibald C. Harrison, Joseph L. Hirsh, Howard A. Kelly and Arthur M. Shipley. Dr. William Pepper, Philadelphia, delivered an address on "The Medical Life of Benjamin Franklin." A portrait of Dr. F. E. Chatard was presented to the faculty by Dr. John W. Williams, and Dr. Harry Friedenwald presented a portrait of Dr. Nathaniel G. Keirle, and also a copy of "Studies in Rabies," by Dr. Keirle. Dr. G. Milton Linthicum, president of the Medical and Chirurgical Faculty, of Maryland, received the gifts.

MICHIGAN

Case of Leprosy Found.—A case of leprosy is reported in Calumet. The patient is a Finn who was in the government employment in Alaska five years ago. The diagnosis has been confirmed by Dr. A. S. Warthin of the University of Michigan.

Shacks for Tuberculosis Patients.—At a meeting of the executive committee of the Antituberculosis Society of Ann Arbor, November 30, it was voted to erect open-air shacks at the University Hospital with accommodation for eight patients, and one at the Homeopathic Hospital to accommodate four patients.

Personal.—Dr. William A. Stone has resigned as assistant superintendent of the Michigan State Hospital, Kalamazoo, and Dr. Herman Ostrander has been appointed his successor.——Dr. Allen L. Cory has been elected president of the Stanton Antituberculosis Society.——Dr. James H. Dempster, Detroit, has succeeded Dr. Herbert M. Rich as editor of the *Detroit Medical Journal*. Dr. Rich remains on the staff as collaborator in the department of pediatrics.

County Society Meets.—The annual meeting and election of officers of the Bay County Medical Society was held in Bay City, December 13. The retiring president entertained the society at a banquet, after which the following officers were elected: President, Dr. John W. Hauxhurst; vice-president, Dr. Roy C. Perkins; secretary, Dr. Hubbard N. Bradley; treasurer, Dr. Charles H. Baker; delegate to the state society, Dr. William R. Ballard, and alternate, Dr. John McLurg, all of Bay City.

NEBRASKA

Poliomyelitis Contagious.—The Nebraska State Board of Health has decided that anterior poliomyelitis, which is now prevalent in the state, is contagious and has ordered the establishment of quarantine.

Bequest to Hospital.—M. M. Gregorian, a day laborer who came to this country from Armenia a quarter of a century ago, and who died recently at Norfolk, has bequeathed $1,000 to the Methodist Hospital, Omaha, and $1,000 each to two hospitals in New York City.

Personal.—Dr. Alexander Bear, Norfolk, for forty years a practitioner of north Nebraska, has retired and moved to his old home in Richmond, Va.——Dr. DeWitt C. Bryant, Omaha, is taking a tour of the world.——Dr. John I. McGirr, Beatrice, has been appointed first lieutenant and assistant surgeon Medical Corps, Neb. N. G., and has been assigned to the first machine gun company.——Dr. and Mrs. Walter O. Henry, Omaha, and Dr. Leslie M. Stearns, Kearney, have returned from Europe.

Society Meetings.—At a meeting of the physicians of Jefferson county, in Fairbury, December 3, the Jefferson County Medical Association was reorganized with the following officers: President, Dr. George A. Heath, Fairbury; vice-president, Dr. Thomas J. Andrews, Fairbury; secretary-treasurer, Dr. Samuel E. Hawes, Fairbury; delegate to the state society, Dr. Gibbert Pritchett, Fairbury; alternate, Dr. George A. Heath, Fairbury; and censors, Drs. J. S. Taylor, Steele City; Harry Brown, Daykin, and Herman Kunze, Fairbury.——At the annual meeting of the Lancaster County Medical Society, held in Lincoln, December 4, the following officers were elected: Dr. John T. Hay, Lincoln, president; Dr. Laurence B. Pilsbury, Asylum, vice-president; Dr. Francis A. Graham, Lincoln, secretary-treasurer; and Drs. Francis A. Graham and Edward W. Rowe, Lincoln, delegates to the state medical society.

NEW YORK

To Relieve State Hospitals.—In order to relieve the congestion of the state hospitals for the insane near New York City, the State Lunacy Commission purposes to erect seven large cottages, each capable of housing 200 patients. Six of these cottages will be erected in connection with the Long Island Hospital, three at Central Islip and three at Kings Park; the other one will be on Wards Island. These buildings will cost about $750,000.

Examination of Water Supplies.—At the recent sanitary conference at Rochester, it was announced that the State Hygienic Laboratory had increased its facilities by establishing a station for the sanitary investigation of water supplies, in the more immediate neighborhood, at Cornell University, Ithaca, N. Y. Health officers, who will find this laboratory more conveniently located for examination of the water supplies of their districts, have been notified. The laboratory will endeavor to make examination and control analysis of each water supply in the district at least once a month. Regular reports will be published for the information of citizens. An invitation has been extended to all health officers and others interested in the maintenance and improvement of the potable waters of New York state to visit this laboratory and familiarize themselves with its methods.

New York City

The Guild of St. Luke.—A number of physicians met at Cathedral College, December 8, and organized a society by this name to be in affiliation with similar societies throughout Europe. This organization has for its object the study of the ethical and historical problems connected with medicine. Dr. Charles E. Nammack was elected president; Drs. Thomas Addis Emmet and Jose M. Ferrer, vice-presidents; Drs. Thomas F. Reilly and James J. Walsh, secretaries.

Physical Defects in School Children.—The official report of Dr. Edwards A. Park, in charge of the examination made during the summer of more than a thousand school children from the tenements with the view of determining the need of open-air schools in New York City shows that of 1,233 children examined, 289, or 23 per cent., showed the characteristic reaction after having been subjected to tests for tuberculosis. In many of these, however, the focus of tuberculosis was walled off and was not likely to exert a serious influence on the general health. There were 50 cases of enlarged tonsils and adenoids; decayed teeth were very general with the result that it was difficult to determine whether the numerous cases of enlarged glands of the neck were due to them or to tuberculosis. Five cases of endocarditis were noted.

Art Commission Approves Designs.—At the recent meeting of the Municipal Art Commission, the designs for the new Bellevue Hospital were approved. It is estimated that this group of buildings will cost $2,750,000, and will consist of two surgical pavilions, a building used for operating rooms, surgical wards and rooms for the house staff and an extension to the laundry rooms and store rooms. This group of buildings will be erected on the blocks east of First avenue between Twenty-sixth and Twenty-ninth streets. The commission also approved designs for three open-air concrete tuberculosis pavilions, arranged with movable sashes so that they can be enclosed and used for other contagious diseases at certain times of the year. These pavilions will be placed on the east side of North Brother Island, and will cost about $35,000 each.

OHIO

Medical Society Meetings.—The second annual banquet of the Starling-Ohio Medical Alumni Association of the Miami Valley was held in Dayton, November 30, under the presidency of Dr. Clifton L. Patterson, Dayton, Dr. Francis C. Gray acting as toastmaster. The following officers were elected: President, Dr. John W. Millette; vice-president, Dr. Charles W. Salisbury; secretary-treasurer, Dr. G. W. Richie, and trustee, Dr. Ned D. Goodhue.——Articles of limited partnership have been filed by Dr. George Strobach, John Rawley, and Walter M. Goodwin, Cincinnati, for the American Physicians' Protective Association. The object of the organization is to aid physicians and surgeons in the collection of their accounts, to keep them properly advised as regards non-paying patients, to eliminate fraudulent practitioners, and to keep the profession advised as to all proposed legislation.

PENNSYLVANIA

Personal.—Dr. J. Edward Nickel, who has been for the past year a member of the staff of the State Sanatorium, Mont Alto, has resigned and will resume private practice in Harrisburg.——Dr. David J. McCaa has been reelected president and Dr. John F. Mentzer, treasurer of the Ephrata Borough Board of Health.——Dr. Howard Y. Pennell has been elected secretary of the reorganized board of health of Downingtown.

Officers Elected.—At the annual meeting of the Berks County Medical Society, held in Reading, December 15, the following officers were elected: President, Dr. George W. Kehl, Reading; vice-presidents, Drs. Franklin P. Lytle, Birdsboro, and Clara S. Keiser, R[illegible]ary, Dr. Henry P. Brunner, Reading; [illegible], Dr. Ralph A. Harding, Reading; rep[illegible]fevre, Reading; censors, Drs. Daniel Longaker, Fremont W. Frankhouser and Israel Cleaver, all of Reading; curator, Dr. Harry F. Rentschler, Reading; librarian, Dr. Clara S. Keiser, Reading, and trustee, Dr. Abraham S. Raudenbush, Reading.——The Jefferson Alumni Association of Northwestern Pennsylvania held its annual meeting and banquet in Scranton, December 16. About forty-five were present, and Professors W. M. Late Coplin and John M. Fisher, of the college, were present and responded to toasts. Dr. John B. Mahon, Pittston, was elected president; Dr. Frederick L. Van Sickle, Olyphant, vice-president, and Dr. J. Norman White, Scranton, secretary.

Philadelphia

Druggists Bid on Work for Poor.—Thirty-one druggists have offered to put up prescriptions issued by the city authorities to poor persons, and their bids were opened December 14 in Director Neff's office. There was $8,000 available for this purpose this year. The basis of the charge is that the drugs are to cost the same as the prices quoted to the municipal hospitals, which is lower than the ordinary wholesale cost.

New Surgical Prize.—A precedent was established in the Medical School of the University of Pennsylvania, December 10, when the Undergraduate Medical Association endowed a surgical prize to be competed for by fourth-year medical classes, beginning 1910. All prizes, heretofore, have been founded by the faculty or alumni. The contest will be for the best essay based on observations of the University Hospital clinics in anatomy, pathology and physiology. The first prize will be $75, and the committee of judges comprises: Drs. Charles H. Frazier, John Speese, and J. Edwin Sweet.

Personal.—Dr. W. Harper Sloan was acquitted of the charge of criminal malpractice before the Court of Common Pleas, December 17.——Dr. S. Lewis Ziegler, who has been seriously ill with erysipelas, is convalescent.——Dr. Leo Loeb, assistant professor of pathology at the University of Pennsylvania, has resigned to become director of a special skin and cancer laboratory in St. Louis.——Dr. Arthur J. Davidson has been elected orthopedic surgeon to the Mathilde Adler Loeb Dispensary of the Jewish Hospital.——Dr. William Jackson Merrill has been elected assistant orthopedic surgeon to the St. Agnes Hospital.

WISCONSIN

County Society Meeting.—At the annual meeting of the Waukesha County Medical Society, held at the State Tuberculosis Sanatorium, Wales, Dr. Albert J. Hodgson, Waukesha, was elected president; Dr. Richard E. Davis, Waukesha, vice-president; Dr. Laurel E. Youmans, Mukwonago, censor; Dr. Michael R. Wilkinson, Oconomowoc, delegate to the state society, and Dr. Daniel McL. Miller, Oconomowoc, alternate.

Treatment of Rabies.—The Pasteur Institute for the treatment of those affected with rabies, recently established at the University of Wisconsin, Madison, in connection with the State Hygienic Laboratory, has had 14 patients up to Dec. 10. Dr. Mazyck P. Ravenel, professor of bacteriology at the University of Wisconsin, is in charge of the institute, and Dr. Cornelius A. Harper is making the injections. It is planned to establish a boarding-house for the patients.

GENERAL NEWS AND COMMENT

Conference on Hookworm.—The first conference on the eradication of hookworm will be held in Atlanta, Jan. 18 and 19, 1910. Delegates will be appointed to the conference from Alabama, Mississippi, South Carolina, Georgia and Florida.

Pellagra.—A special commission has been appointed, with the approval of the Secretary of the Treasury, for the investigation of pellagra. Five members are from the Public Health and Marine-Hospital Service, and two from the staff of St. Elizabeth's Insane Hospital at Washington.

Personal.—Dr. Edward C. Ellett, Memphis, Tenn., was elected chairman of the Section on Ophthalmology of the Southern Medical Association, and Dr. Urban S. Bird, Tampa, Fla., secretary.——Dr. John R. Minahan, Green Bay, Wis., has been elected president of the Association of Surgeons of the Chicago, Milwaukee and St. Paul Railway.

Resolutions Regarding Dr. Nauman.—At a recent meeting of the American Medical Association of Vienna, a resolution was adopted setting forth the high appreciation the members of the association have for Dr. Henrick Nauman of the University of Vienna as an investigator and teacher of otology. Dr. Nauman is soon to visit the United States.

Soo Line Surgeons Elect.—At the annual meeting and banquet of the Minneapolis, St. Paul and Sault Ste. Marie Railway Surgical Association, held in Minneapolis, December 16, Dr. Justus Ohage, St. Paul, was elected president; Dr. Herbert B. Crommett, Amery, Wis., vice-president; and Dr. John H. Rishmiller, Minneapolis, secretary-treasurer. The next meeting will be held in St. Paul.

Fake Drug Inspector.—A letter of warning has been sent out by the United States Department [illegible] certain individuals who are falsely [illegible] as agents of the department for the purpose of obtaining money. One John H. Kraft is specifically mentioned as an impostor, whose *modus operandi* is to call on individuals suffering from rheumatism, for whom he offers to provide treatment at a cost of fifty dollars, five dollars of which are to be paid down and the balance within five years.

No Tuberculosis Prize as Yet.—The statement in the newspapers that a prize of $100,000 has been offered to the person who discovers a cure for tuberculosis, that Yale University is custodian, and that members of the faculty of Yale Medical School are to act as trustees, is stated by Prof. Herbert E. Smith, dean of the medical faculty, to be incorrect. The possibility of securing such a fund was suggested and information was asked as to the conditions to be attached to such a prize, but aside from this conference, nothing has been done and the authorities of Yale University do not know that anything further will come of the matter.

Another Scheme to Defraud.—A correspondent from Nebraska City, Neb., calls attention to another scheme to obtain some of the earnings of the hard-working but too good-natured physician. An individual purporting to be a land agent calls on the doctor offering him a lot in a new town in some distant state, as Texas or Oklahoma, on payment of the cost of the abstract and deed ($4 to $7), the latter to be sent later. In return the physician is to speak a good word for, or furnish a list of probable investors in, the project being promoted. The physician gives up the money but the deed is *not* forthcoming.

Seaboard Physicians Meet.—At the annual meeting of the Seaboard Medical Association, held in Norfolk, Va., Dec. 7, 8, and 9, the following officers were elected: President, Dr. William T. Parrott, Kinston, N. C.; vice-presidents, Drs. Joseph Grice, Portsmouth, Va., B. H. Halsey, Suffolk, Va., and Herbert D. Walker, Elizabeth City, N. C.; secretary, Dr. J. Rainey Parker, Goldsboro, N. C.; treasurer, Dr. Israel Brown, Norfolk, Va. (reelected), and orator, Dr. Joseph H. Hiden, Pungoteague, Va. The chief addresses of the meeting were delivered by Drs. Southgate Leigh, president, Norfolk, Va., on "The Education of the Public on the Cancer Problem," by Dr. William T. Parrott, Kinston, S. C., on "The Student Doctor," and by Dr. Charles P. Wertenbaker, U. S. P. H. and M.-H. Service, on "Pellagra." Kinston, N. C., was selected as the place of meeting for 1910.

Work of the Marine Hospital Service.—The summary of transactions of the Public Health and Marine-Hospital Service for the fiscal year of 1909 shows that during the year no further cases of human plague occurred in San Francisco, but that 4 cases of rat plague were found, the last on Oct. 23, 1898. There were 156,059 rats caught, of which 93,558 were examined. In Oakland no human plague occurred until October 26, when a case was reported that had received its infection in Contra Costa county. In Los Angeles, Aug. 11, 1908, a case of human plague was discovered, and soon after an infected ground squirrel was found. No case of human plague was discovered in Seattle, but out of 48,652 rats examined, 10 were found infected. A widespread plague infection among ground squirrels was found in Contra Costa county, and up to October 30, 44,843 squirrels had been destroyed. During 1908, 111 deaths from rabies were reported, from 534 infected localities. The disease prevailed in 38 states and territories in the eastern three-fourths of the United States, but no cases were reported from the Rocky Mountain or Pacific Coast regions. The report also deals with the investigations now being pursued on pellagra and the hookworm disease. The leprosy investigation station at the Island of Molokai, for which $100,000 was appropriated, is now completed and ready for occupancy. At this station experiments on animals, in which quantities of leprosy material are required, will be carried on, but the investigation of incipient cases will be continued at the temporary laboratory in Honolulu. The problems which leprosy present include the successful growth of the lepra bacillus on artificial media, the successful inoculation of the lower animals, the discovery of a substance analogous to tuberculin to be used as a remedial or diagnostic agent, the discovery of the mechanism whereby the infection spreads from one person to another, and lesser problems that add to the knowledge of the disease, and while apparently of no great immediate importance, may indicate the path leading to the solution of the greater problems. During the year 24,657 cases of smallpox were reported with 75 deaths from 42 states, 1 territory, and the District of Columbia. The additions to the hygienic laboratory, which treble the capacity of that institution, were completed during the year and nine bulletins were issued. The publication of a series of bulletins embodying a digest of comments on the Pharmacopeia was undertaken. There were 966,124 immigrants inspected during the fiscal year, 14,536 of whom were certified for rejection on account of physical defects. At the hospital for immigrants, Ellis Island, 6,186 patients were admitted for treatment during the year. In the 21 marine hospitals owned by the government and at the 126 other stations, where seamen of the merchant marine received hospital and dispensary treatment, there were treated during the year 53,074 patients. Physical examinations were made of 4,980 persons connected with various branches of the service. The personnel of the service at the close of the fiscal year included the surgeon-general, 5 assistant surgeon-generals, 35 surgeons, 66 passed assistant surgeons, and 21 assistant surgeons. There were also 279 acting assistant surgeons and 45 pharmacists.

FOREIGN

Epidemic of Trichinosis in Spain.—The town of Jimena in Spain reports 30 cases of trichinosis in persons who had eaten the pork from a certain hog. Fourteen of the victims had died at the date of the report and trichinæ were found in the muscles.

Medal for Local Health Officer.—The town of Santa Margherita in northern Italy has recently had a medal engraved and presented to Dr. A. Alberti who for fifty years has been the local health officer, in token of appreciation of his long and devoted service to the commonwealth.

Degrees Conferred by University of Brussels.—On its seventy-fifth anniversary recently the university of Brussels conferred honorary medical degrees on Waldeyer of Berlin, Metchnikoff of Paris, the chemist E. Fischer of Berlin, and Duke Karl Theodor of Bavaria, whose death was announced a few days later.

Monument Proposed.—The town of Hilden in Germany plans to erect a monument to its greatest son, Guilelmus Fabricius, the eminent surgeon, who upheld the standard of science after the death of Ambroise Paré in France. It is desired to unveil a statue of Fabricius on the three hundred and fiftieth anniversary of his birth, June 25, 1560.

The Sanitary Aspect of the Russian Political Exiles.—Last September the two editors of the official organ of the Russian National Medical Association were arrested at Moscow for publishing a revolutionary article in their journal. They were acquitted, however, when they produced proof that the article in question was merely the publication of the answers that had been received to a question-blank sent out by the medical association to reliable men, mostly physicians, who had been exiled, inquiring of them in regard to the sanitary conditions of the "deportation system" as they had experienced them. Only 24 replies were received, and all were printed. Among the statements to which the government objected was one to the effect that innocent parties were frequently sent into exile by mistake for the one actually incriminated, and that the guards in charge of the troop of exiles mistreated them and violated the women exiles. These statements were proved true by specific instances. Dr. A. Dworetzky of Moscow writes to the *Münchener med. Wochenschrift*, Nov. 23, on the subject, relating a number of details from the various replies received to the question blanks. Only 11 of the 24 writers had been able to obtain employment in their new home; the government does not permit the exiles to teach or practice law; physicians alone are allowed to practice their profession. A monthly allowance of from $2.50 to $4.00 is given the exiles by the state—their sole support. It is a frequent practice to send exiles from the south of Russia to the far north of Siberia, where almost all soon die of tuberculosis. Medical aid is not obtainable unless one of the party happens to be a physician. In the cemetery at Kolymsk for the exiles, the graves are filled with suicides, the conditions at that terminal station wrecking the strongest nervous system.

LONDON LETTER

(From Our Regular Correspondent)

London, Dec. 11, 1909.

Damages from Hotel for Serving Typhoid Oysters

Lieutenant Cardale of the Royal Navy sued the proprietor of a hotel at Chatham where he and a friend ate oysters. After a fortnight both were taken ill with typhoid fever and the friend died. A month before, the health authorities had warned against the eating of contaminated shellfish from the Medway, the river on which Chatham is built. The jury awarded the plaintiff $1,320 damages and costs.

The Housing and Town Planning Bill

The bill for the regulation of housing and town planning, just passed, is one of the most important advances in sanitary legislation ever made in this country. Previously the building of towns was in no way regulated and property owners were able to construct new streets without any regard for the public interests. By the new act every county council is obliged to have a health officer who must devote the whole of his time to the work and therefore not engage in private practice. At present in many cases the health officer is a general practitioner who devotes only part of his time to his public work. He must be supplied with reasonable information by the health officers of the several districts in the county. According to a previous act houses let to the working classes must be in all respects fit for human habitation, but this applies only where the annual rent does not exceed $100 in London, $65 in Liverpool, $50 in Manchester and Birmingham, and $40 elsewhere. The present act extends this provision to houses with an annual rental not exceeding $200 in London, $130 in a borough or urban district, and $80 elsewhere. These new provisions will render the act applicable to practically all the working class dwellings throughout the country. According to a previous act local authorities were empowered to provide new houses for the working classes, but this clause was only in force where it had been adopted by the local authority. By the present act it is put in force in every district throughout the country. Further, if a local authority does not provide accommodation necessary for the working class of that district, the local government board may hold an inquiry and declare the local authority in default, and order them to do what is necessary. The provisions of the act with regard to town planning mark a new departure in legislation in this country. Hitherto new centers of population have been allowed to grow up and existing urban areas have been allowed to expand without control or prevision. The result has often been the haphazard development of land in the vicinity of urban centers has produced slums, prevented the orderly growth of towns, and later involved enormous expenditure in clearing sites, widening streets, and providing necessary open spaces. The act aims at securing, in the future, sanitary conditions and convenience by enabling schemes to be made under which building land will be developed with due regard for future requirements. Local authorities are empowered to prepare town planning schemes in connection with land likely to be used for building purposes or to adopt any such schemes proposed by the owners of land. But the plans must be approved by the central health authority—the local government board.

The Seventeenth International Congress of Medicine

This will be held in London in 1913. The National Committee of Great Britain and Ireland at the last congress, under the presidency of Dr. F. W. Pavy, F.R.S., will be made into a general committee to meet in February. It has been decided that the colonies are to be adequately represented.

The Medical Treatment of London School Children

As stated in previous letters the problem of providing medical treatment for London school children suffering from disease or defects which prevent or interfere with their education, now compulsory, is subject of much controversy. For economical reasons the London County Council has declined to establish school clinics, but instead has come to an arrangement with certain hospitals to treat the children. This arrangement has been censured by the British Medical Association and by medical opinion in general. The council entered into agreements with eight hospitals to provide treatment for 16,000 children suffering from disease of the eyes, ears and skin, and accepted the offer of Charing Cross Hospital to provide *x*-ray treatment for twenty-five children suffering from ringworm. It is remarkable that the council has not seen its way to provide dental treatment, as the prevalence of disease of the teeth is appalling.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Dec. 10, 1909.

Proposed Tax on Mineral Waters

The proposition to tax mineral waters, which has several times been suggested in our country, has always been systematically rejected. It is probable that the same fate awaits the project of the minister of finances, who proposes to introduce a stamp-tax on mineral waters, a label bearing a guarantee being attached to each bottle. This project has called forth numerous protests, not only from merchants, but from the public. Mineral waters, are, in fact, regarded as hygienic drinks. *To augment their price is to restrict their use among* people of small means. The opponents of the tax point out, moreover, that the official guarantee stamp will have a harmful effect by conferring a sort of equality on all waters of one region and thus creating most regrettable confusion in the minds of the consumers. From the fiscal point of view, the returns from the tax will be very small, the waters subject to the tax amounting to about 30,000,000 bottles. By a tax of 1 cent (5 centimes) a bottle, only about $300,000 (1,500,000 francs) will be raised, and, moreover, the greater part of this amount will be absorbed by the expenses of collecting the tax, which is characterized by its adversaries as "the tax on public health."

An Important Prosecution for Fraud in Flour

A few days ago arguments in an important case of frauds in flour began, before the court of Limoux, department of l'Aude; 32 merchants or middlemen are implicated. The two principals are men of Italian origin settled in the vicinity of Limoux. The 30 others are merchants or brokers of Perpignan, Milhau, Valence and various other cities throughout France. The two manufacturers put on sale products of undefined composition (intended, according to their prospectuses, to whiten flour), in which analysis has revealed the presence of considerable proportion of talc. Over 200,000 pounds (100,000 kg.) have been used in adulteration of flour sold by the accused.

Freedom of Choice of a Physician by Subjects of Charity

At its recent congress, the National Association of Mayors of France passed a resolution that recipients of charity should have the privilege of selecting their physicians and pharmacists.

Measures Against the Illegal Practice of Medicine

In a preceding letter, I mentioned the case of an individual who, though without any diploma, had been able to practice medicine with impunity for several years. Public opinion was strongly aroused by this affair, and the Prime Minister has just called the attention of the mayors to the obligations which rest on them to restrict the practice of medicine to the medical profession. He has particularly recommended that they see that the diplomas of practitioners should be regularly registered within the space of a month as the law prescribes, and that students of medicine called to practice during an epidemic, or to fill a vacancy temporarily, should furnish testimonials of scholarship.

Election of Dr. Mosny to the Academy of Medicine

In the course of its session of December 8, the Academy of Medicine elected an honorary member in the section of hygiene and sanitary police. Dr. Mosny, physician of the St. Antoine Hospital and member of the consulting committee of public hygiene, was elected by 65 out of 78 votes.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Dec. 1, 1909.

Personal

Professor Kern, heretofore subdirector of the Kaiser Wilhelm academy for army medical instruction, who has made a name for himself by the publication of a number of excellent philosophic treatises, will resign his position and will be followed by Dr. Keitel from Breslau.

Professor Wiedersheim at Freiburg has been chosen a member of the newly founded academy of sciences at Heidelberg.

Dr. Jordan, professor extraordinary for surgery at Heidelberg, a talented pupil of Professor Czerny, succumbed at the age of 45 to a recurrence of a mediastinal tumor.

Professor Kraft, formerly conductor of Brehmer's sanatorium at Görbersdorf has taken the directorship of Lahmann's sanatorium, "The White Stag" (*Weissenhirsch*) in place of Professor v. Düring.

Infant Mortality at Charlottenburg

The efforts of our neighboring city Charlottenburg to reduce infant mortality show some success for 1908. The mortality of children for first year of life reckoned for 100 living amounts to 12.5. The following figures show the gradual reduction of mortality in Charlottenburg. For 1880: 33.67; 1885: 28.75; 1890: 25; 1895: 22.60; 1906: 14.16 for 100 born living.

Medical Certificates for Candidates for Matrimony

A petition has been presented to the federal council (*Bundesrat*) and the Reichstag which proposes as a supplement to the legal requirements for marriage license that both of the engaged persons shall present the certificate of a licensed physician, stating that he has been consulted medically by both parties with reference to the contemplated marriage. In this way the result will be reached that those who contemplate marriage will be informed regarding their state of health without any restraint being placed on their free choice in other respects. The petition is founded on the idea that the essential necessity of health in the parties to a marriage should be brought to the consciousness of the public. By the proposed legal regulation many weak and diseased persons would be restrained from matrimony. In this way the previous annual increase of population would be diminished, to be sure, but only to the benefit of the public, for the condition of health would be gradually improved. It is not to be denied that the fundamental idea of this petition is correct. It is very much to be wished that those who desire to enter the marriage state should recognize the duty to inform themselves regarding the health of each other quite as much as regarding the financial relation and other fundamental requisites of a satisfactory marriage. Every physician can cite examples of the carelessness in regard to health with which marriage is often contracted and what serious consequences arise from this neglect.

Tuberculosis Mortality for 1908

According to the latest official information 33,205 men and 30,115 women died of tuberculosis in Prussia in 1908. Reckoned for 10,000 living, this gives for 1908 a proportion of 16.46. This figure is the smallest (except for the year 1906) which has been reached since 1875 when the first Prussian statistics were published. In 1875 the entire number of those who died of tuberculosis in the kingdom of Prussia was 82,122 or 31.9 per 10,000. The reduction in the absolute number of deaths from tuberculosis is the more remarkable in consideration of the steady increase in population. In 1908 the population amounted to 38,473,129.

Improvement of Village Hygiene

In order to improve the hygiene of the villages which is for the most part in a sad condition, so-called prizes for cleanliness have been founded in certain districts of Alsace which are annually distributed to the villages which have best fulfilled the conditions for that year. Of ten communes which announced themselves for the competition this year, one village obtained the first prize of $250 (1,000 marks) and two communes shared the second prize, $125; in addition each of the three communes received a diploma.

Care for Alcoholic Patients

For about fifty years efforts have been made in Germany to improve the moral and physical condition of those addicted to drink by treatment in inebriate asylums (*Trinkerheilanstalten*) and to restore them to self support. The first of these benevolent establishments was founded by the evangelical deaconess institute of Duisburg in the little Rhenish city of Lintorf. At present there are in Germany 47 inebriate asylums with 1,429 beds in all. Among them are 10 private sanatoria and 6 institutions which receive other patients in addition to alcoholics. In the remaining 31 public institutions about 15,000 patients were received in 1907. Moreover according to official statistics about 12,000 patients with chronic alcoholism were treated annually from 1877 to 1901 in the general hospitals of Germany. If the first three years, 1877 to 1879, inclusive are compared with the last four years, 1898 to 1901, an increase of the annual average of cases of chronic alcoholism from 5,240 to 18,207 is seen. While it must be admitted that with the increase in the number of hospitals and with the decrease in the public dread of such institutions, proportionally more patients undergo treatment in the hospitals, yet on the other hand, it is apparent from the figures given that a very undesirable growth of chronic alcoholism has occurred and it must be concluded that the number of inebriate asylums and the care for inebriety in general are not yet as advanced as is desirable. The newly founded bureau for the instruction and care of alcoholic patients will supply a need in this direction.

The Russian Consultation Bureau

The affair of the Russian consultation bureau which I have repeatedly treated in previous letters, i. e., the charges raised against a number of Berlin professors of paying Russian interpreters and agents for the introduction of Russian patients has reached a termination for some of the affected persons. The physician who brought the whole affair into public notice requested an investigation by the medical court of honor for himself on account of the complaints raised that he had carelessly impugned the honor of his colleagues without sufficient grounds. He was acquitted, the court deciding that his suspicions were not baseless. It appears to be established that several physicians and professors were guilty. Certain accused professors, however, against whom a disciplinary process had been instituted by the department of education have been acquitted of every charge as the official preliminary investigation has shown that there was no sufficient ground for official interference. This result concerns Professors v. Leyden, Ewald, and Senator. The two last named had resigned their offices in the Berlin Medical Society on account of the charges (the first that of librarian, the latter that of the first president). The new election was postponed till the situation should be cleared. Now a new election has occurred and as was to be expected Senator was reestablished. On the other hand to our astonishment Ewald was not re-elected. This most regrettable affair has been settled in a satisfactory manner at least so far as the three accused professors are concerned. It seems, however, that the official process begun against some other professors is to take its course and it is the impression that they will not escape punishment entirely.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Dec. 2, 1909.

Dangerous Trades

In the course of a trial against a firm of celluloid-makers medical experts were heard with a view to ascertaining the dangers of this trade and the best means of preventing accidents. In the case in question a fire broke out on the premises, which were not at all fit for this kind of work; the arrangements for ventilation and removal of celluloid dust were especially unsatisfactory and eighteen persons were suffocated by the poisonous gases before they could escape. As the trade is developing very much lately in this country and several serious accidents occurred, medical societies took the question up and presented a memorandum to the board of trade urging the cooperation of medical men with technical experts being made obligatory in all such manufactories. It has been estimated that the risk run by the laborers in this trade is equaled only by that incurred by the makers of phosphorus matches, but in the latter case slow chronic disablement is produced; in the case of the celluloid workers a quick death ensues. Another point emphasized in the medical memorandum is danger in the employment of juveniles in this trade because of the natural carelessness and the lack of experience among boys and girls of 15 to 17 years. The medical action has been commented on very favorably by the lay press.

Another danger to public health has been brought to the notice of the board of trade by a private action of firms on the occasion of the death of a very influential banker in Vienna, who was said to have been poisoned by the tapestry in his office. Post-mortem examination showed that antimony and arsenic had been inhaled for a long time by the unfortunate money magnate. The only source of the poisonous substances found was traced to the imported heavy tapestry, said to come from England, which was used lavishly in the offices of the bank. Some twenty years ago, wall-paper containing a trace of arsenic in the bright green and red colors was used extensively in this country, and when some deaths were caused by these paper-hangings, its use was forbidden. Nevertheless, strict inspection of the stock in the hands of the firms trading with material for wall-papering was at once instituted recently in order to assure the public that no danger was threatening. This insight into the relation between public health and business is largely due to the presence of a few level-headed men of our profession on the board of health. In this country of the unexpected it is not at all a matter of course that a board of health should comprise any medical men. At all events, attention was directed recently to the necessity of protecting the population against unscrupulous money-making by certain trades at the risk of the health of the consumers.

The Transactions of the Meeting of the Austrian Medical Councils

At the meeting of the above-mentioned bodies which has become a yearly institution welcomed by the profession, several important decisions were adopted. Dr. Grün read a paper on quackery, pointing out that lately several cases of acquittal of quacks had occurred in spite of the proved menace to public health that this meant. The position of the medical profession was seriously compromised unless this condition of the present attitude of the courts was changed. The law was rather elastic on this point. Therefore, he recommended the following amendment to the quackery act to be considered by the meeting. "Whoever undertakes to treat or treats continually, with or without payment, one or more persons, without possessing an inland university medical diploma, or a foreign recognized degree, is guilty of an offence against the law, unless he can prove that his immediate interference was the means of saving the life of the affected person. The penalty inflicted should not be less than one month, and not more than three months' imprisonment."

Several articles of the proposed new *Aerzte Ordnung*, or medical act, were severely criticized which will be discussed shortly in the parliament. Dr. Gruss showed that throughout the entire act the medical practitioner has been put under heavy obligations without receiving an equivalent of rights. Thus the law requires the doctor to report certain diseases, all cases of trauma, of injury, and attempts at suicide, while it does not protect him against claims by patients arising out of his complying with these requirements of the law.

Another point much discussed was the question of specialists. Dr. Löwenstein moved the following resolution: "The titles obtained from an appointment by the state or a municipal institute may be used by the holders of these posts only, and must be relinquished when the appointments cease. A doctor may call himself specialist only after having served at least one year at a special department of a hospital and if he adopts this title, he may not practice anything else but his specialty. If several special branches of the profession belong together, these may be united; local requirements may necessitate the combination of different branches. Such combinations will have to be recognized by the local medical council."

Correspondence

Davis Memorial Fund

To the Editor:—The committee appointed to secure funds for the Davis memorial feels assured that the medical profession is in a large degree ignorant of its scope and purpose. This committee was appointed at the Portland session of the Association and at once organized in the expectation of securing the fund promptly.

The national disaster caused by the destruction of San Francisco induced the committee to defer its work in the interest of the medical profession of California. The financial crisis of two years ago was sufficient reason for causing a still further delay. The committee thinks that the time has now arrived for pushing its work to a completion. The committee has requested of the various state societies to take this matter actively in hand and name the sum which seems to them an equitable apportionment. The committee has suggested that half of the respective sums be furnished by a vote of the society, thus causing indirectly the enrolment of every member of the profession in contributing toward this worthy object. The committee feels sure that the other half of this apportionment will be gladly furnished by private subscription, as a privilege rather than a burden. This plan was adopted in Massachusetts and on a personal appeal of the chairman the subscription greatly exceeded the sum allotted. We feel assured that an effort of this sort, inaugurated by the officers of the state medical societies, will be successful. The committee urges the different state organizations to complete their subscriptions without further delay, knowing that the great body of the medical profession feels a debt of gratitude which can be publicly expressed only in this way.

We would ask every reader of The Journal to take up this matter actively with the officers of the state society. The funds should be forwarded to Dr. Frank Billings, treasurer of the American Medical Association, 100 State Street, Chicago.

Henry O. Marcy, Chairman of the Committee, Boston.

Pharmacology

Radical Revision of the Pharmacopeia

It is interesting to note that pharmacists are moving in the direction of a radical revision of the Pharmacopeia. At the May meeting of the Baltimore branch of the American Pharmaceutical Association the following resolutions were offered and accepted for future discussion:

> *Resolved,* That it is the sense of the Baltimore Branch of the American Pharmaceutical Association that the Ninth Revision of the U. S. Pharmacopeia should not contain formulas for compound preparations and should present matter relating to simples and preparations of simples, only; that the National Formulary should contain only such formulas for compound preparations as are consistent with prevailing advanced knowledge of chemistry, pharmacology, pharmacy and therapeutics and that all titles therein contained should be true to content and in accord with accepted medical and pharmaceutical ethics. It is further
>
> *Resolved,* That the parent body be requested to consider the advisability of publishing a General Receipt Book, with frequent supplements, to contain all formulas dropped from the U. S. P. and N. F., and such other formulas as may be useful to pharmacists.

Mr. H. P. Hynson, a pharmacist of Baltimore, discusses these resolutions in a recent paper (*Bull. Am. Phar. Assn.,* November, 1909) in which he says that the effect of such a rule would be to dismiss about 40 articles from the Pharmacopeia, or 3 per cent. of the pharmacopeial titles, relegating them to the National Formulary. For instance: Cataplasm of kaolin, antiseptic solution, and the compound acetanilid powder would not be admitted, and compound mixture of glycyrrhiza, compound syrup of sarsaparilla and some other well-known mixtures would have to be dismissed. A broad construction of the resolution would not necessitate the dismissal of preparations in which a small amount of another substance is added for the purpose of effecting solution, but slight changes should be made in the titles and formulas, whereby such preparations might be made to comply with the new rule. Solution of iodin in solution of potassium iodid of sufficient strength need not be called compound solution of iodin.

He thinks that it would not be wise to offer argument on either side at the present time. "The whole subject, however, will be more clearly considered," he says, "if we fix in our minds just what the pharmacopeia of to-day should be. Is it to be an authority as to standards, alone; standards of identity characteristics; standards of pharmacodynamic or adjuvant worth; standards of relative potency, or is it to be a book of both standards and suggestions? Its chemistry and pharmacy must be beyond reasonable question, but it can scarcely presume to establish therapeutic standards or even attempt to do so, when so little has been done to make such standards possible."

The proposition is one of considerable importance and may be taken as pointing to a distinction to be made between the Pharmacopeia and the National Formulary. It is questionable if the dismissal of compound formulas from the Pharmacopeia would be desirable if there were no other official standard book. As the National Formulary has been in a sense legally recognized and is now generally accepted as containing official preparations, there could be no objection to assigning all compound mixtures to that book. This would logically involve the authorization of the National Formulary by the same representatives of the medical and pharmaceutical professions as now determine the character of the Pharmacopeia. Or if this is not feasible and it is deemed advisable to continue the work as a publication of the American Pharmaceutical Association, the value of the book might be enhanced if physicians should cooperate in its preparation.

The Public Service

Medical Corps of the Navy

Changes for the week ended Dec. 18, 1909:

Benton, F. L., surgeon, detached from the *Franklin* and ordered to the *Prairie.*

Shippen, L. P., asst.-surgeon, detached from the Naval Prison, Portsmouth, N. H., and ordered to the *Prairie.*

Steep, J., P. A. surgeon, detached from the Naval Station, Newport, R. I., and ordered to the *Franklin.*

Baker, M. C., asst.-surgeon, detached from the *Ohio* and ordered to the Naval Recruiting Station, Cincinnati.

Clifton, A. L., asst.-surgeon, detached from the Naval Recruiting Station, Cincinnati, and ordered to duty in connection with the fitting out of the *Michigan* and to duty on board that vessel when placed in commission.

Public Health and Marine-Hospital Service

List of changes for the seven days ended Dec. 15, 1909:

White, J. H., surgeon, granted 8 days' leave of absence from Dec. 11, 1909.

Stoner, J. B., surgeon, on being relieved by P. A. Surgeon R. H. Creel, directed to proceed to Port Townsend, Wash., and assume command.

Blue, Rupert, surgeon, granted 4 months' leave of absence from Jan. 1, 1910, with permission to go beyond the seas.

Lavinder, C. H., P. A. surgeon, granted 4 days' leave of absence from Dec. 13, 1909, under paragraph 191, Service Regulations.

Lumsden, L. L., P. A. surgeon, granted 7 days' leave of absence from Nov. 29, 1909, under paragraph 191, Service Regulations.

Corput, G. M., P. A. surgeon, granted 16 days' leave of absence from Dec. 15, 1909.

Korn, W. A., P. A. surgeon, granted 1 day's leave of absence, Dec. 22, 1909.

Schereschewsky, J. A., P. A. surgeon, granted 5 days' leave of absence, under paragraph 191, Service Regulations.

Wille, C. W., P. A. surgeon, granted 2 days' leave of absence from Dec. 8, 1909.

Francis, Edward, P. A. surgeon, granted 6 days' leave of absence from Dec. 6, 1909, under paragraph 191, Service Regulations.

Creel, R. H., P. A. surgeon, relieved from duty at Baltimore and directed to proceed to Evansville, Ind., and assume temporary command. Granted 1 day's leave of absence en route to station.

Pettyjohn, Joseph, P. A. surgeon, relieved from duty at San Francisco and directed to proceed to New Orleans and report to the medical officer in command for duty and assignment to quarters. Granted 1 month's leave of absence en route to station.

de Valin, Hugh, P. A. surgeon, directed to proceed to Washington, D. C., and report to the Director of the Hygienic Laboratory for temporary duty.

Hunt, [illegible] nic Laboratory, de[illegible] Association for the [illegible], to be held in Bosto[illegible] ary 1.

Altree, G. H., acting asst.-surgeon, granted 4 days' leave of absence from Nov. 2, 1909, without pay.

Bailey, C. A., acting asst.-surgeon, granted 20 days' leave of absence from Dec. 12, 1909.

Branham, H. M., acting asst.-surgeon, granted 3 days' leave of absence from Dec. 15, 1909, without pay.

Foster, S. B., acting asst.-surgeon, granted 22 days' leave of absence from Dec. 10, 1909.

Safford, M. V., acting asst.-surgeon, granted 7 days' leave of absence from Dec. 7, 1909, under paragraph 210, Service Regulations.

Watson, H. J., acting asst.-surgeon, granted 19 days' leave of absence from Dec. 13, 1909.

BOARD CONVENED

Board of medical officers convened to meet at Montreal, Canada, Dec. 6, 1909, for the purpose of examining an alien. Detail for the board: Passed Assistant Surgeon Eugene H. Mullan, chairman; Acting Assistant Surgeon C. K. Russel; Acting Assistant Surgeon Handsford McKee, recorder.

Health Reports

The following have been reported to the Public Health Service, during the week ended Dec. 17, 1909:

SMALLPOX—UNITED STATES

Alabama: Montgomery, Nov. 20-27, 23 cases.
California: San Francisco, Nov. 20-27, 1 case.
Colorado: Fruita, Nov. 20-27, 8 cases.
Connecticut: Stamford, Nov. 1-30, 1 case.
Indiana: Marion, Nov. 27-Dec. 4, 1 case; South Bend, Nov. 23-30, 4 cases.
Kansas: Independence, Nov. 27-Dec.4, 2 cases.
Louisiana: New Orleans, Nov. 27-Dec. 4, 1 case.
Michigan. Bay City, Nov. 28-Dec. 4, 3 cases.
Minnesota: Duluth, Nov. 20-Dec. 4, 4 cases.
Mississippi: Brookhaven, Oct. 30-Nov. 6, 1 case; Natchez, Nov. 20-27, 5 cases.
Missouri: St. Louis, Nov. 27-Dec. 4, 3 cases.
Montana: Stevensville, Nov. 20-27, 1 case.
North Carolina: Charlotte, Nov. 20-Dec. 4, 8 cases; Hickory, Oct. 30-Nov. 6, 1 case; Nov. 20-27, 3 cases.
Ohio: Dayton, Nov. 20-Dec. 4, 6 cases, 1 death.
Tennessee: Memphis, Nov. 20-27, 2 cases; Nashville, Nov. 27-Dec. 4, 1 case.
Texas: Paris, Nov. 20-27, 29 cases.
Vermont: Smithfield, Nov. 20-27, 1 case.
Wisconsin, La Crosse, Nov. 20-27, 1 case; Superior, 1 case.

SMALLPOX—INSULAR

Porto Rico, Nov. 1-30, 10 deaths.

SMALLPOX—FOREIGN

Brazil: Bahia, Oct. 22-Nov. 5, 32 cases, 26 deaths; Rio de Janeiro, Oct. 24-Nov. 1, 3 cases.
Chile: Valparaiso, Oct. 30-Nov. 6, present.
India: Bombay, Nov. 2-9, 1 death; Madras, Oct. 23-29, 1 death; Rangoon, Oct. 16-23, 1 death.
Indo-China: Saigon, Oct. 16-23, 1 case, 1 death.
Italy, general, Nov. 14-21, 16 cases; Naples. 6 cases, 2 deaths; Turin, Oct. 21-28, 1 case.
Java: Batavia, Oct. 16-23, 5 cases, 1 death.
Mexico: Aguascalientes, Nov. 14-21, 3 deaths; Chihuahua, 1 case; Mexico City, Oct. 30-Nov. 6, 1 death; Monterey, Nov. 21-28, 1 death.
Portugal: Lisbon, Nov. 13-20, 11 cases.
Russia; Libau, Nov. 7-14, 5 cases, 1 death; Moscow, Oct. 23-Nov. 6, 4 cases, 1 death; Odessa, Oct. 23-Nov. 13, 19 cases, 4 deaths; Riga, Oct. 23-30, 7 cases; St. Petersburg, Oct. 5-Nov. 13, 94 cases, 36 deaths; Warsaw, Sept. 18-Oct. 9. 10 deaths.
Spain: Almeria, Oct. 1-31, 3 deaths; Barcelona, Nov. 8-22, 2 deaths; Valencia, Oct. 23-30, 1 case.
Straits Settlements: Singapore, Oct. 9-16, 1 death.
Tripoli: Tripoli, Oct. 31-Nov. 13, 7 cases.

YELLOW FEVER

Brazil: Manaos, Nov. 6-13, 1 death; Para, Nov. 6-20, 6 cases, 3 deaths.
Ecuador: Guayaquil, Oct. 31-Nov. 13, 8 deaths.
Mexico: Merida, Nov. 29, 1 case; Peto, Nov. 26, 1 case.

CHOLERA

India: Bombay, Oct. 27-Nov. 9, 4 deaths; Calcutta, Oct. 9-16, 7 deaths; Oct. 23-30, 9 deaths; Rangoon, Oct. 16-30, 7 deaths.
Japan: Osaka, Nov. 17, 1 case.
Java: Batavia, Oct. 26, present.
Manchuria: Dalny, Oct. 9-16, 2 deaths; Oct. 25-Nov. 1, 2 deaths.
Russia in Asia: Vladivostok, Sept. 22-Oct. 21, 115 cases, 83 deaths.
Russia in Europe, general, Oct. 31-Nov. 6, 172 cases, 78 deaths; St. Petersburg, 81 cases, 20 deaths; St. Petersburg, government, 22 cases, 11 deaths.

PLAGUE

Brazil: Bahia, Oct. 22-Nov. 5, 7 cases, 3 deaths; Rio de Janeiro, Oct. 25-Nov. 1, 2 cases.
China: Hankow, Dec. 7, present.
Ecuador: Guayaquil, Oct. 9-23, 21 deaths; Oct. 30-Nov. 13, 34 deaths.
India, general, Oct. 23-30, 4,287 cases, 3,456 deaths; Bombay, Oct. 27-Nov. 9, 11 deaths; Calcutta, Oct. 9-16, 5 deaths; Oct. 23-30, 10 deaths; Rangoon, Oct. 16-30, 6 deaths.
Indo-China: Saigon, Oct. 9-23, 5 cases, 5 deaths.
Japan: Kobe, Nov. 17, present; Osaka, Nov. 17, 1 case.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DENATURED ALCOHOL

To the Editor:—Please tell me what denatured alcohol is, its chemical composition, uses, etc. R. F. LISCHER, Mascoutah, Ill.

ANSWER.—Denatured alcohol is alcohol to which has been added certain materials which destroy its character as a beverage and render it unfit for liquid medicinal purposes, but which do not prevent its employment for industrial purposes. Denatured alcohol is exempt from the internal revenue tax laid on ordinary alcohol, and is sometimes called tax-free alcohol. Under authority of an act of Congress passed in 1907, the Commissioner of Internal Revenue has prescribed that for general purposes alcohol known as completely denatured alcohol must be prepared by either of the following formulas:

1. To every 100 gallons ethyl alcohol (of not less than 180 degrees proof) there shall be added 10 gallons of approved methyl alcohol and one-half gallon of approved benzin.

2. To every 100 gallons of ethyl alcohol (of not less than 180 degrees proof) there shall be added two gallons of approved methyl alcohol, and one-half gallon of approved pyridin bases.

The methyl alcohol, benzin, and pyridin intended for use as denaturants must be submitted for chemical test and must conform to certain specifications. In cases in which the above named substances would render the alcohol unfit for certain industrial uses special denaturants have been authorized.

Tax-free alcohol can be economically used as a fuel or for power in place of gasoline and is used mechanically as a solvent, etc., in various trades. In manufacturing, alcohol is employed in the production of a number of extensively used chemicals, such as ether, chloroform, acetic ether, etc. It finds extensive application in the manufacture of varnishes, photographic dry plates, embalming fluid, lacquers, pastes and varnishes from soluble cotton, thermometer and barometer tubes, celluloid, transparent soap, photoengravings, fulminate of mercury, watches, purified rubber, imitation leather, and for many other purposes.

Book Notices

MEDICAL JURISPRUDENCE, FORENSIC MEDICINE AND TOXICOLOGY. By R. A. Witthaus, A.M., M.D., Professor of Chemistry, Medical Jurisprudence, and Toxicology in Cornell University and Tracy C. Becker, A.B., LL.B., Counsellor at Law, Professor of Criminal Law and Medical Jurisprudence in University of Buffalo, with the collaboration of various authors. Second Edition. Cloth. Vol. III. Pp. 982, with illustrations. Price, $6 per vol. Sold by Subscription only. New York: William Wood & Co., 1909.

The third volume of this handbook treats of the medicolegal relations of the special senses, of insanity and mental unsoundness of marriage and divorce, of the *x*-rays, and of blood, and other stains and of the hair. The medicolegal relations of insurance also receive a special chapter. The volume is introduced by an extensive list of cases cited in the volume. As in the previous volumes, the work is painstaking and exhaustive. Insanity is treated in two articles, one by E. D. Fisher from a medical point of view and the other by T. C. Becker and C. A. Boston from the legal side. The latter article discusses the relations of mental unsoundness to testamentary capacity and to contracts and other business relations as well as to criminal responsibility. The statutes relating to the care and custody of incompetent persons are given in a separate article. The scientific portion of the book, including *x*-ray examinations and the examination of blood, semen, hair, etc., is well executed and well illustrated. The work terminates with an index to the first three volumes. This volume forms a very important part of this valuable work and it is to be hoped that the succeeding volume will sustain the high standard already set.

PYE'S SURGICAL ion. Revised and
Largely Rewritten b B.A., M.B., B.C.,
F.R.C.S., Surgeon-in-C . Mary's Hospital.
Cloth. Pp. 576, with , 4 net. New York:
E. B. Treat & Co., 1909.

The standard work of the late Walter Pye, which has gone through several editions, has been revised and largely rewritten. The editor has brought up to date the description, details and application of treatment occurring in surgical practice, at the same time maintaining in great measure the character and style adopted by the original author.

Manual of Diseases of the Ear. By Thomas Barr, M.D., Lecturer on Diseases of the Ear, Glasgow University, and J. Stoddart Barr, M.B., Ch.B., Assistant to Lecturer on Diseases of the Ear, Glasgow University. Fourth Edition. Cloth. Pp. 477, with Illustrations. Price, $4.50. New York: The Macmillan Co., 1909.

This book has been largely rewritten, with the aid of J. Stoddart Barr, son of the senior author. It is intended for students, and fulfils its purpose by being short and crisp, but withal really comprehensive and up to date. It presents the characteristics of the better class of books written by English authors in omitting most of the considerations which are not yet ripe for immediate practical application and giving almost exclusively and in a categorical fashion the authors' own views and therapeutic directions. It must, however, be granted that a full familiarity with the literature and current views of others is shown. It is pleasing reading, and can be recommended as a work for the student or for brief references, but not for those who seek fuller details.

An Introduction to Chemical Analysis for Students of Medicine, Pharmacy and Dentistry. By Elbert W. Rockwood, M.D., Ph.D., Professor of Chemistry and Toxicology and Head of Department of Chemistry in the University of Iowa. Cloth. Third Edition. Pp. 241, with 20 illustrations. Price, $1.50. Philadelphia: P. Blakiston's Son & Co., 1909.

The facts of physical chemistry have been freely utilized in this work and ionic explanations given to the analytical reactions. The work is well adapted to the instruction of the medical student who needs in his study of analytical chemistry, not so much to become an expert analyst as to gain a clear insight into the principles of chemistry and sufficient technic to fit him for the simple analytical work which he may have occasion to undertake in his practice. Sufficient quantitative work is given to familiarize the student with some volumetric methods; and some special work in toxicology and sanitary chemistry complete the volume. This work ought to prove very acceptable to teachers of chemistry in medical schools or to students in college preparing for medicine.

Quain's Elements of Anatomy. Editors, Edward Albert Schäfer,
LL.D., Sc.D., F ... y and Histology in the
University of ... ton, M.D., F.R.S., Pro-
fessor of Anato ... of Belfast, and Thomas
Hastie Bryce, ... tomy in the University
of Glasgow. ... Neurology. By E. A.
Schäfer and J. ... taining the Descriptive
Anatomy of th ... the Organs of Special
Sense. Elevent ... with Illustrations. Price,
15 shillings net ... reen & Co., 1909.

This volume contains the descriptive anatomy of the peripheral nerves and of the special sense organs. The portion of the book dealing with macroscopic anatomy has been written by Prof. Johnson Symington and the microscopic portion by Professor Schäfer. This edition contains much new matter and a large number of new illustrations, including many original drawings by Prof. Ramon y Cajal. The principal new matter is in the portion devoted to microscopic anatomy, the description of the gross anatomy of the cerebrospinal nerves and their distribution being naturally more conventional. The section devoted to special sense organs is particularly good, especially the chapters on the eye and ear. The plan of issuing the work in small and convenient sections is convenient, especially for students.

The Practical Medicine Series. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Vol. VII, Pediatrics, Edited by Isaac A. Abt, M.D., Assistant Professor of Medicine (Pediatrics Department), Rush Medical College, with the Collaborations of May Michael, M.D., Orthopedic Surgery, Edited by John Ridlon, A.M., M.D., Professor of Orthopedic Surgery, Northwestern University Medical School, with the Collaboration of A. Steindler, M.D. Cloth. Pp. 234. Price, $1.25. Chicago: The Year Book Publishers.

This volume, intended for the general practitioner, gives a review of the year's literature of the world on the subjects of pediatrics and orthopedic surgery. Under pediatrics, the subject of hygiene and dietetics are especially well represented. Completeness is given to the dietetic section by a translation of an article by Prof. E. Feer, which is credited to the *Bulletin of the Chicago School of Sanitary Science*, July 31, 1909. It comprises eighteen pages in the book and reviews the whole subject in an admirable way. Like the other numbers of the series, this volume will provide the general practitioner with a valuable summary of the year's progress in this special subject.

Sechsundachtzigster Jahres-Bericht der Schlesischen
Gesellschaft für ... Enthält den General-
bericht über die ... der Gesellschaft im
Jahre 1908. Pap ... Buchhandlung, 1909.

This Silesian society comprises various sections, of which the medical is of the most interest to the physician. The report of the sessions of the medical section begins with an address by Professor Hürthle on the occasion of the unveiling of a bust of Purkinje, giving an account of the life and scientific activities of Purkinje. Among the other notable articles is one by A. Peiser on the therapy of sarcoma and another on the same subject by Goebel, a discussion on the pathology and therapy of chronic cardiospasm by Gottstein, a paper on the pathology of adrenal tumors by Winkler, and a review of the progress in our knowledge of syphilis by A. Neisser.

Marriages

A. R. L. Dohme, M.D., Baltimore, Md., to Miss Paula Carl, at Boston, November 22.

William Emil Durr, M.D., to Mrs. Adeline B. Fink, both of Milwaukee, November 25.

Ella K. Dearborn, M.D., and Arthur G. Herald, both of Portland, Ore., December 1.

David W. Walley, M.D., to Miss Rosa Alperque, both of Richton, Miss., December 12.

George Frederick Reinhardt, M.D., to Miss Aurelia Henry, both of Berkeley, Cal., recently.

Herman Gross, M.D., Metuchen, N. J., to Miss Goldie Altman, of New York City, December 1.

Leland O. Mauldin, M.D., Greenville, S. C., to Miss Carrie Mason Floyd of Woodruff, S. C., October 27.

Edgar H. Lancaster, M.D., Houston, Texas, to Miss Ellen Waggoner, of Austin, Texas, December 2.

Thomas Morris Chaney, Jr., M.D., Old Fort, N. C., to Miss Myrtle McComless, at Asheville, N. C., December 9.

Hal Clarke Smith, M.D., Sunnyside, Neb., to Miss Bertie Isabelle Wilson of Long Pine, Neb., at Omaha, December 1.

Deaths

Frank W. Reilly, M.D. Northwestern University Medical School, Chicago, 1861; Illinois Army Board, 1861; a member of the American Medical Association, American Public Health Association, and Chicago Academy of Medicine; assistant Health Commissioner of Chicago; veteran of the Civil War; pioneer sanitarian and editor; died at his home in Chicago, December 16, from arteriosclerosis and cerebral hemorrhage, aged 73. He was a native of England, and after studying in the Medical College of the State of South Carolina, Charleston, and Rush Medical College, Chicago, graduated from Chicago Medical College, and served that institution as demonstrator of anatomy. At the outbreak of the Civil War he enlisted as a volunteer surgeon and was seriously wounded at the battle of Shiloh; he later served as assistant surgeon of the Forty-fifth Illinois Volunteer Infantry and surgeon of the Twenty-sixth. From 1867 to 1873 he was sanitary inspector and assistant commissioner of the Chicago Health Department; and then entered the United States Public Health and Marine-Hospital Service. After the yellow fever epidemic in Memphis, he was made sanitary inspector of the National Board of Health, and placed in charge of the sanitary regeneration of the city, and of the Mississippi Valley. In 1881 he was made a member of the Illinois State Board of Health, and four years later became an editorial writer on the Chicago *Morning News*, and then was made managing editor. In 1891, he was again appointed a member of the Illinois State Board of Health, and was made its secretary, and three years later he reentered the Chicago Health Department and was made assistant commissioner of health in 1895. In 1873, while assistant commissioner of health, he served as editor of a monthly magazine called *Hygiene*, in which he inaugurated and urged a national campaign for health and hygiene. He was one of the committee of three who directed the educational campaign for a pure water supply, which established the feasibility of the drainage channel. He conceived and carried out the idea of publishing a weekly health bulletin, containing facts about the mortality and morbidity of Chicago, and setting forth the simpler lessons of public hygiene for the education of the public in the prevention of disease. While he was assistant secretary of the State Board of Health, the medical practice act of the state was put in force. Along the lines of sanitation and preventive medicine, Dr. Reilly's achievements were most noteworthy; and his services to public health have been of inestimable value to the city, state and nation.

Ferdinand Charles Valentine, M.D. Missouri Medical College, St. Louis, 1876; a member of the American Medical Association and a well-known specialist in genitourinary diseases, of New York City; died at his home in Belle Harbor, L. I., December 13, from arteriosclerosis and cardiac dilatation, aged 58. He was a native of Havenstadt Leer, Hanover, Germany. After his graduation from Missouri Medical College, he received a degree in medicine from the University of Guatemala, C. A., in 1879, and became a member of the Medical faculty of Guatemala, San Salvador and Honduras, and was for nine years surgeon general of the latter republic. He was emeritus professor of genitourinary diseases in the New York School for Clinical Medicine, and consulting genitourinary surgeon to the Manhattan State and Red Cross hospitals.

James Louis Harrington, M.D. University Medical College of Kansas City, Mo., 1889; a member of the Missouri State Medical Association; instructor in clinical genitourinary surgery in the School of Medicine in the University of Kansas; secretary of the Kansas City Post Graduate Medical College and Hospital since its organization; died at his home in Kansas City, December 8, from heart disease, aged 42. At his funeral the faculty of the Post Graduate Hospital Medical School attended in a body.

Albert Henry Blanchard, M.D. Harvard Medical School, Boston, 1851; a member of the Massachusetts Medical Society; surgeon of the Forty-first Massachusetts Volunteer Infantry and Third Massachusetts Volunteer Cavalry during the Civil War; for nearly 40 years a member of the school committee of Sherborn, and for most of that time its secretary; died at his home, December 5, aged 81.

Charles Henry Bogman, M.D. Jefferson Medical College, Philadelphia, 1871; a veteran of the Civil War; from 1874 to 1881, surgeon of the Union Pacific Railroad at Winnemucca, Nev., and surgeon general of Nevada on the staff of Governor Kincaid; died at his home in Zanesville, Ohio, December 6, from heart disease, aged 66.

David Todd Stuart, M.D. University of Virginia, Charlottesville, 1901; formerly a member of the American Medical Association, and a resident of Paducah; a medical missionary of Soo Chow, China; died November 6, near that city, from an accidental gunshot wound, while hunting, aged 31.

Frank E. Dewey, M.D. University of Buffalo, N. Y., 1873; of Peterboro; a member of the Medical Society of the State of New York; formerly health officer of the town of Smithfield; coroner of Madison county; died suddenly in Oneida, December 6, from heart disease, aged 60.

Robert Earle Conklin, M.D. College of Physicians and Surgeons, Chicago, 1905; a member of the American Medical Association; coroner of Harlan county, Neb.; died at his home in Alma, December 12, from an overdose of atropin, accidentally administered by a nurse, aged 31.

William Newton Klase, M.D. Medical College of Virginia, Richmond, 1889; a member of the American Medical Association; for two years chief examiner of a life insurance company in Cincinnati; died at his home in Carbondale, W. Va., November 26, aged 57.

Thomas Norton, M.D. Long Island College Hospital, Brooklyn, N. Y., 1878; formerly a member of the American Medical Association; a member of the Medical Society of the State of California; died at his home in San Luis Obispo, Cal., October 30, aged 63.

Chauncey Z. Williams, M.D. Tulane University, New Orleans, La., 1890; a member of the Louisiana State Medical Society, and mayor of Covington for nearly fourteen years; died in the New Orleans Sanitarium, December 6, after a surgical operation, aged 44.

George F. Keiper, M.D. Rush Medical College, Chicago, 1865; formerly a member of the state legislature of Nebraska, and superintendent of the Norfolk State Hospital for the Insane; died in San Diego, Cal., December 10, from carcinoma of the stomach.

William Brashear Pusey, M.D. University of Louisville, Ky., 1887; a member of the American Medical Association; a specialist in diseases of the eye, ear and throat; died at his home in Louisville, December 6, from acute nephritis, aged 43.

Thomas Peare Sappington, M.D. University of Maryland, Baltimore, 1869; a member of the Medical and Chirurgical Faculty of Maryland; of Unionville, Md.; died in a sanitarium at Catonsville, Md., December 8, from nephritis, aged 62.

Lindsey S. Brown (license, registration, Wis., 1899); a member of the State Medical Society of Wisconsin; an oculist and for forty-one years a practitioner of Madison; died at his home, November 24, from cerebral hemorrhage, aged 69.

Arthur Page Belew, M.D. University of Virginia, Charlottesville, 1870; a member of the Medical Society of Virginia, and vice-president of the Shenandoah County Medical Society; died at his home in Edinburg, December 4, aged 61.

John Watts Miller, M.D. Medical College of Virginia, Richmond, 1861; surgeon in the Confederate Service during the Civil War; of Sulphur Springs, Tex.; died at the home of his daughter in that place, November 28, aged 77.

Harrison H. Guthrie, M.D. Rush Medical College, Chicago, 1863; a surgeon during the Civil War; and later a practitioner of Minnesota; died at his home in San Bernardino, Cal., November 30, from senile debility, aged 77.

Charles M. Fisher, M.D. Kansas City (Mo.) Medical College, 1900; a member of the Kansas Medical Society; died at his home in Hanover, Kan., December 6, from pneumonia following typhoid fever, aged 35.

Joseph Lester Johnson, M.D. Bellevue Hospital Medical College, New York City, 1891; a member of the Medical Society of the State of New York; died at his home in Riverhead, L. I., December 2, aged 40.

Fidelia Green Campbell, M.D. College of Physicians and Surgeons, Boston, 1890; Salisbury, Mass.; died in the Homeopathic Hospital, Newburyport, Mass., December 4, after a surgical operation, aged 55.

James Pinkerton, M.D. Medical Department of Victoria College, Cobourg, Ont., 1865; a resident of North Dakota for more than a quarter of a century; died at his home in Rolla, December 7, aged 75.

Henry H. Harris, M.D. University of Pennsylvania, Philadelphia, 1860; a member of the Medical Society of the State of North Carolina; died at his home near Wake Forest, December 6, aged 75.

James H. C. Robinson, M.D. Kansas City Hospital College of Medicine, 1885; a practitioner of Missouri since 1856; died at his home in St. Joseph, December 3, from senile debility, aged 77.

John Sylvester Brown, M.D. New York University, New York City, 1891; was found dead in his apartments in Sacramento, Cal., December 1, from dilatation of the heart.

Gilbert Hopkins Swezey, M.D. Bellevue Hospital Medical College, New York City, 1869; of Bay Side, N. Y.; died at North Falmouth, Mass., October 6, aged 68.

Thomas Clark Coleman, M.D. Gate City Medical College, Texarkana, Tex., 1905; of Malta, Tex.; was shot and killed in that place, December 3, in an affray.

George Edmund Husband, M.D. Hahnemann Medical College, Chicago, 1861; died at his home in Hamilton, Ont., October 1, from cerebral hemorrhage, aged 70.

Frank Rieser, M.D. Pennsylvania Medical College, Gettysburg, 1852; died at his home in Reading, Pa., December 4, from heart disease, aged 79.

Thomas Maxwell Carroll, M.D. Cincinnati College of Medicine and Surgery, 1874; died at his home in Springfield, Ohio, December 7, aged 71.

Charles Galen Smith, M.D. Jefferson Medical College, Philadelphia, 1897; died at his home in Beaver Springs, Pa., September 29, aged 34.

Joseph W. Reynolds (registration, Md., 1892); died at his home in New Bridge, Md., November 25, from disease of the stomach, aged 74.

Charles Kelly Myers, M.D. Cincinnati (Eclectic) 1849; died at his home in Stockton, Cal., October 13, from cerebral hemorrhage, aged 81.

Edward Francois Painchaud, M.D. McGill University, Montreal, 1848; died at his home near Klotzville, La., December 5, aged 86.

Cuthbert Reese Barham, M.D. University of Virginia, Charlottesville, 1890; died recently at his home in Boykins, Va., aged 41.

John J. Mitchell, M.D. University of Louisville, Ky., 1875; died recently at his home in Beaver Dam, Ky., aged 62.

George W. Sullivan (license, Mo., 1883); died at his home near La Belle, Mo., December 1.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Lodge Practice in Pennsylvania

Dr. G. D. Thomas, writing from Meadville, Pa., regarding the efforts made by the local physicians to repress lodge practice and contract work, says: "It is surprising how easy it was to convince those physicians engaged in this work that it was wrong in principle, and how readily it was abandoned. Without bitter condemnation, but with friendly reasoning, every doctor in the city signed the resolution agreeing to cease contract practice work for lodges and fraternal societies. The fact that for $2 a physician was expected to treat for a year all members of a family under 18 years of age, be the members two or a dozen, was easily shown to be unfair to the public and an injustice to the profession. The public, with few exceptions, see the matter in the same light, and up to the present, no one has been prevailed on to come from the outside to enter into a contract to do the work abandoned by local physicians."

The essential and distinguishing feature of objectionable contract practice, as shown in last week's Journal, is the existence of a middleman who buys the physician's services at wholesale and sells them at retail, thus farming out the physician to the public under an agreement whereby the physician gets a pittance and the patient gets poor services, while the middleman alone, who reaps the difference as his profit, is the gainer. If the question can be placed in this, the true light, before both the public and the profession, there is little doubt as to the outcome.

Postgraduate Course

The postgraduate program was given last week.

Suits for Fees and Malpractice Not Allowed to be Consolidated

The First Appellate Division of the Supreme Court of New York says, in the case of Martin vs. Prentice (118 N. Y. S. 215), that the defendant, a physician, sued the plaintiff in the municipal court for professional services. Two days later, and before answer in the municipal court, the plaintiff began this action for damages for malpractice. Thereon an order was made, consolidating the municipal court action with this action, and authorizing the defendant physician to interpose as a counterclaim in this action the matter alleged as a cause of action in the municipal court. But that order could not be sustained. Section 817 of the New York Code of Civil Procedure authorizes a consolidation of two or more actions in favor of the same plaintiff against the same defendant, where the causes of action are such as may be joined. Section 818 authorizes such a consolidation where one of the actions is pending in another court, when this court may remove the action and consolidate it with an action pending here. But the two sections must be read together, and are applicable only where they are in favor of the same plaintiff. Such was not this case, and the sections cited furnished no authority for the order. The defendant had a right to bring his action in the municipal court, a forum of his own choosing, and could not be compelled to abandon that forum and interpose his demand as a counterclaim in an action which he could not control in another forum. But Justice Laughlin, while agreeing that the court was without jurisdiction to consolidate the two actions, says that he is of opinion that the Supreme Court should have stayed proceedings in the action in the municipal court until the trial and determination of this action, because the municipal court did not have jurisdiction to award the plaintiff in this action the judgment which he demanded against the physician for malpractice, and a judgment in the municipal court in favor of the physician for his services would bar the action for malpractice.

Physical Examination Refused as Interference with Trial

The Supreme Court of Georgia holds, on the appeal of Macon & Birmingham Railway Co. vs. Ross (65 S. E. R. 146), that the power of a trial court to require a plaintiff, suing for a physical injury alleged to be permanent, to submit to an examination by a competent physician, at the instance and expense of the defendant in order to ascertain the nature, extent, and probable duration of the injury, is one to be exercised or not according to the sound discretion of the presiding judge, under the facts of the case; and a refusal to require such a submission will not be reversed, unless his discretion has been abused. And where the motion for a new trial showed that a motion of the character above indicated was made several times during the progress of a trial, but was refused by the presiding judge on the ground that he could not grant the application without interfering with and delaying the trial, and there was nothing to show any abuse of discretion in such ruling, a reversal will not be granted on that ground.

2. **Infantile Scurvy Involving the Hip Joint.**—Jacobsen reports two cases. The first patient, a boy a little less than a year old, had always been weak, and not until he was seven months old was he able to sit up alone. Prior to that time his back had been too weak to support him, although he was fat and when lying down gave one the impression of being well. On Thanksgiving day, 1908, he fell from a chair, striking on his left hip and thigh, although there had been no evident bruise. The extremity could not be moved or even touched without causing great pain. For several months prior to the receipt of this injury, the child's gums had repeatedly bled. He had also had frequent discharges of blood with the movements of his bowels. The child apparently was well-developed, but pale and fretful. He would begin to cry as soon as he was lifted out of bed. There was no apparent wasting or deformity of the extremities. The left leg and thigh were held in a flexed position. The right leg could be moved freely without causing any pain and no other part of the body was evidently affected. However, the slightest manipulation of the left lower extremity caused him to cry out. There were no changes in the gluteal cheek nor in the creases between the nates or below the buttock. There was, however, marked fixation of the hip associated with exquisite tenderness. The gums were found spongy and bled easily. The child had been brought up on a patent food. Recognizing the condition to be one of scurvy, the dietary was changed. Because of the very acute and evidently marked disturbance in and about the joints weight extension was applied for a time. Immediately improvement followed and within a very short time the child was free from pain, slept naturally, and began to improve in color and vigor.

The first evidence of disturbance in the second case had been observed during the early days of November, 1908. In attempting to put on the child's shoes he would cry, and from this time on there was marked pain in his lower extremities, more pronounced in the right than in the left. While affecting both hip joints, there was also some disturbance in the knee. It was impossible to raise the child out of bed, because at each effort to lift him he cried out. The child had had nose-bleed frequently for about 6 months, and for 2 months there had been daily hemorrhages from the gums. Examination did not disclose any swelling or marked change about the knee joints, except that they were very sensitive. The hip joints, particularly the right one, were rigid and tender. There was no wasting of the thighs or buttocks and no indication of muscular atrophy so characteristic of hip joint disease. The gums were swollen and spongy, especially in the neighborhood of the upper central incisors. This child was being fed on peptogenic milk powder. After the change in his dietary and without any medication or attention to the local condition, the patient improved at once and within a week was entirely free from pain and discomfort.

3. **Disguised Starvation.**—According to Rosewater, disguised starvation is prevalent everywhere from an unconsciously insufficient food intake (mainly from economy, worry, and ignorance), causing an atonic state and rendering the underfed powerless to maintain normal function, susceptible to many intercurrent diseases, unable to resist tuberculous and other infections, while tending toward mental and physical bankruptcy. The lower animals follow instinct, especially instinct of appetite, because possessing no other controlling faculty. Man's highest faculty, reason, presides over his instincts—appetite, fullness, satiety, etc., giving to these due but not undue credence and weight in deciding and controlling his final acts. The application of this hitherto unrecognized principle regarding the control of our wants by reason is as follows: Man's yielding to overindulgence of food through uncontrolled appetite, also his repeated refusal to eat through lack of appetite are, as a rule, physiologic errors and injurious to health. Having no appetite is no excusable criterion for insufficient eating, since man possesses abundant processes for digesting his food, even without appetite, and can force himself to eat, in spite of lack of appetite, fulness, or even disgust, through the supreme control and guidance, by his reasoning faculties, of his force of will.

To save all these classes from the results of disguised starvation, the public should be educated to know by tables of normal weight and height; those too far to either side of the normal range, should be taught to use good reason, judgment, and will, so as to get within the normal range by controlling the quantity, quality, and time of their meals.

Under the supremacy and influence of man's reasoning faculties, his strong desire for drink and drugs, and his other habits are restrained and controlled, his despondency and other vicious mental and nervous states that inhibit or depress his normal functions are overcome by hope assured, cheerfulness, and other human virtues substituted as tonics for his vices.

4. Abstracted in THE JOURNAL, Sept. 25, 1909, p. 1047.

5. **Lymphomata of Lachrymal and Salivary Glands.**—Ziegler reports two cases of what is known as Mikulicz's disease. Both patients were colored. In the first case no medicine was administered, but the tonsils were thoroughly excised. Free breathing was at once established. Retrogression of the submaxillaries began promptly, followed by the parotids, and finally included the lachrymals. In the second case, a double tonsillectomy was performed, and the uvula was excised. The throat healed rapidly. Free nasal breathing was established and the physical condition improved. The first retrogressive symptom noted was the softening of the lachrymal and submaxillary glands after about one month. Ziegler holds that the syndrome of the symmetrical enlargement of the lachrymal and salivary glands is sufficiently characteristic to be accepted as pathognomonic of Mikulicz's disease. The enormous lymph cell infiltration into the interstitial tissue, and the relative passivity of the gland structure, demand that this tumefaction shall be classed as true lymphoma or lymph tumor, as distinguished from adenoma or tumor of the glandular substance. Respiratory obstruction not only hinders the evaporation and drainage of these sinus secretions, but also causes suboxidation and other disturbances of metabolism. It should, therefore, be considered a true etiologic factor. The course of Mikulicz's disease is chronic, but the prognosis is favorable, with a tendency to relapse. The treatment aims to improve lymphatic action and systemic oxidation. All respiratory obstructions must be promptly and thoroughly removed. Extirpation is rarely indicated.

Boston Medical and Surgical Journal

December 9

10 *Relation of Posture to Human Efficiency and the Influence of Poise on the Support and Function of the Viscera. J. E. Goldthwait, Boston.
11 *Treatment of Stricture of the Bulbar Portion of the Urethra by Resection, Partial or Complete. H. Cabot, Boston.
12 *New Treatment for Abdominal Surgical Shock. J. R. Hopkins, Denver.
13 Diagnosis of Ulcer of the Duodenum. E. A. Codman, Boston.

10. **Relation of Posture to Efficiency.**—It is Goldthwait's belief that the way in which our bodies are used, or the attitudes assumed in the performance of all that goes to make up the routine of life, is of greater importance than is commonly supposed. To stand erect, to walk or move easily, to have the various parts of the body so perfectly adjusted that easy balance and graceful use must result, is to be desired for reasons of far greater importance than the esthetic. Such elements are of absolute importance for perfect health and the fullest economic efficiency, since use of the body in proper poise insures the least friction with consequently the greatest amount of energy available for whatever may be required of the individual. This is of importance not only because of the effect on the framework of the body, but because of the effect which it must have on the body as a whole. The human organism resembles in many ways a delicately balanced machine made up of many parts each related to the others, and that which we call perfect health is simply the proper correlation of all of these many parts. As a machine, it is intended for use, and when working rightly there is the minimum of friction, and consequently the efficiency of the individual is the greatest that is possible. Anything which results in a departure from this correlation or balance means strain or friction and represents a distinct waste of energy so that the efficiency is lessened. Under such conditions some one part may be, and usually is, strained more than the others, but it must be remembered, nevertheless, that no one part can be strained without affecting the whole.

11. **Treatment of Stricture of Urethra.**—Originality is not claimed by Cabot for what he describes as a combination of methods used by other operators with such personal modifications as have seemed desirable. With the patient in the lithotomy position, a free median incision is made down to the urethra, dividing the structures of the bulb in the median line and turning them aside. The stricture is then divided by a longitudinal incision about one and one-half inches in length. All excess of scar tissue should be removed, the whole strictured portion excised if necessary, and hemostasis obtained. The anterior segment of the urethra is then freely mobilized by separating the corpus spongiosum from its attachments until it can be joined to the posterior segment without tension. If it is necessary to divide the urethra completely, suturing should be begun on the roof, the sutures being passed from without inward, including all the structures of the corpus spongiosum and the urethra. When it has been found possible to leave the roof of the canal intact, suturing is begun at the sides in such a way that the longitudinal incision in the urethra is brought together transversely, somewhat after the method of a pyloroplasty. After about one-third of the circumference of the canal has been sutured, a No. 28 sound is passed into the urethra and the suture is completed about this so as to be sure that the canal is given full caliber.

The last suture closing the wound unites the two extremities of the longitudinal incision in the urethra, and by lengthening this incision the caliber can be increased to any reasonable extent. Next, the urethra is opened on the sound at a point as far behind the stricture as possible, and just sufficient to admit a No. 12 (English) soft rubber catheter. The wound is then sutured in layers, bringing together the muscular structures of the bulb as accurately as possible with interrupted sutures, and the skin is closed, except for a point at the lower angle through which the catheter is brought out. Resection is said to be applicable to all strictures of the bulbomembranous portion of the urethra not amenable to gradual dilatation and not complicated by infiltration of urine or fistulas.

12. **Abdominal Surgical Shock.**—The treatment advocated by Hopkins is said to be especially suitable for shock during the few hours or days following an abdominal operation, when the patient is not under an anesthetic, although it is probably beneficial when the patient is anesthetized, but not to so great a degree. It is described as follows:

Take out two skin sutures as near the umbilicus as the wound will permit, then pry apart the continuous sutures in the fascia and peritoneum and inject beneath the omentum, if possible behind the transverse mesocolon in the neigborhood of the posterior wall of the stomach, getting as near to the solar plexus as possible, saline solution at a temperature of 112 F. During the first two or three seconds the patient feels little or no pain, only feels that the hot solution is permeating among the intestines, but the remaining two or three seconds is much different; the pain is very severe, for then the splanchnic nerves, the solar and hypogastric plexuses are being strongly irritated by the heat and pressure of the hot salt solution. They are well known to be very sensitive. The patient not being under an anesthetic, the reflexes are not depressed by it. The irritation of the splanchnic nerves and sympathetic ganglia produced by the heat and pressure at once causes contraction of the intestinal arteries, veins and portal vein, and thus a marked rise in blood pressure. Really a shock is produced by the sudden pressure of this hot solution on this great and important part of the vasomotor nerve mechanism, but this shock is a sudden reversal of the phenomena of surgical shock. The radial pulse returns or its pressure is markedly increased. The glass tube is taken out quickly, a small piece of gauze laid over the wound, and a strip of adhesive plaster applied, then a tight abdominal binder to sustain the pressure. If this treatment should not succeed, Hopkins advises repeating it in one or two hours. In addition to the above treatment he uses hot salt solution by rectum, 10 ounces every two hours, principally on account of getting the heat near the hypogastric plexus and splanchnic nerves; also he advises giving full glasses of hot water to drink for similar purposes. Otherwise he does not disturb the patient with hypodermics or even raising the foot of the bed; just keep her warm and as comfortable and peaceful as possible.

2. **Antiseptic and Aseptic Methods.**—Pendlebury and Back show by a comparison of results the superiority of aseptic over antiseptic methods.

3. **Relation of Alcohol to Immunity.**—Parkinson found that alcohol in small quantities has no action on the phagocytic activity, nor has it any action on the phagocytic activity until it is present in 12.5 per cent. strength. Small quantities of alcohol injected into rabbits may stimulate the production of antibodies temporarily. A large dose lowers the opsonic index for 24 hours. Continuous moderate doses cause a permanent lowering of the opsonic index. Parkinson found that the reacting mechanism to vaccines is much less effective in alcoholized rabbits than in normal rabbits; the difference is still more marked when living micro-organisms are used.

10 *Employment of Silver Wire to Bridge Gap after Resection of a Portion of the Lower Jaw. S. White.
11 *Case of "Giant Feet." H. Stevenson.

6. **Syphilis and Aneurism.**—Osler says that at a low estimate we may place the mortality from syphilis at between 6,000 and 7,000 annually, about 1 in 80 of the deaths, not taking into account the unestimated and very large number of stillbirths. In about one-seventh of the cases the deaths are due to what we regard as the more direct effects of the disease; aneurism and the enormous group of affections of the nervous system represent later, but none the less definite, effects of the poison. There are four lines of attack possible. The first is a wholesome and healthy education of our youth in matters sexual, pointing out plainly the necessity of continence, though a hard condition; the really terrible risks, and the sad train of events likely to follow an infection. Secondly, steps should be taken to lessen "the sight of means," as the proverb puts it, the open, flagrant whoredom. Thirdly, venereal diseases should be put in the same category as other acute infections of public dangers, and every case should be known, registered and supervised. Lastly, much may be done to lessen the ravages of the disease by increasing everywhere the facilities for early and prolonged treatment.

7. Published in *The Lancet*, Nov. 27, 1909.

8. **Oxygen Generator and Inhaler.**—Hill's apparatus is intended for use in places and under conditions where cylinder oxygen cannot be obtained easily for patients with heart disease, asthma, etc., who are in a state to manipulate the apparatus, and particularly for use in mountain sickness. Its portability and lightness make it suitable for transport, and it can be used wherever a pint or two of water can be obtained. The apparatus is of less use in cases of pneumonia, etc., in which oxygen can only be tolerated when administered through a funnel or a light mask, and away from big cities where oxygen cylinders cannot be obtained, for successive bag full can be made and the gas pressed out through the funnel or mask. The apparatus consists of a small metal box—the generator—connected with a vulcanized rubber bag—the breathing bag. The bag holds about 15 liters, and ends in a rubber mouthpiece. The bottom of the generator is closed by a screw cap and asbestos washer, and a piece of wire gauze is interposed between the generator and the bag. The mouthpiece is closed with a screw-clip during the generation of gas. Oxygen is generated from sodium peroxid by contact with water, and a solution of caustic soda results. The caustic soda solution is used to absorb the exhaled carbonic acid.

10. **Silver Wire After Resection of Portion of Lower Jaw.**—White removed two inches of the lower jaw of a boy 9 years old for sarcoma. The bone was divided in front at the level of the left canine tooth, and behind just above the junction of the body with the left ramus. The periosteum covering the lower border of the excised segment was carefully preserved. The resected surfaces of the lower jaw were pierced with a drill to the depth of ¾ inches. The drill hole in the body was horizontal, and placed near its lower margin so as to miss the teeth roots; that in the ramus was vertical and somewhat posterior to the mandibular foramen. The ends of a suitable length of stout silver wire were jammed tightly into the drill holes, and the wire completely covered by suturing together the mucous membranes of the cheek and the floor of the mouth over it. The boy can open his mouth almost to the full, and when the jaws are closed the teeth on the right side meet accurately those in the corresponding side of the upper jaw. He is able to bite soft things, and has to be restrained from attempting greater masticatory feats.

11. **Giant Feet.**—This boy, now 4 years of age, was apparently a normal child at birth with the exception of deformity of the toes and some enlargement of the ball of the left foot. At the age of 6 months he was vaccinated, and about the same time lumps in the leg and groin appeared. Gradually the enlargement extended toward the armpit; the arms at the same time getting thinner. Present condition: The two inner toes of the right foot are normal in development, the three outer toes are very much enlarged, resembling small tubers; they are acutely dorsiflexed, and arise from a much thickened sole pad. The left foot is even more deformed, only the inner toe escaping, and the characteristics described on the right side

are more exaggerated. The left leg, thigh, groin, and infrascapular regions are sites of large fatty tumors, while a single large one is also present on the right buttock. When the child is standing there is well-marked lordosis, due apparently to the weight of the tumor in the groin, and possibly to some intra-abdominal growths. The skin is everywhere normal in appearance, and a section from one of the tumors had the ordinary characteristics of a lipoma and presented no evidence of angiomatous structure.

Annales de Médecine et Chirurgie Infantiles, Paris

12 Infantile Scorbutus. (Deux cas de maladie de Barlow.) L. Concetti.
13 *Conservative Treatment of Chronic Glandular Lesions in the Neck. (Traitement des adénites chroniques sousmaxillaires et du cou.) B. G. Alvarez.

13. Treatment of Chronic Inflammation of the Glands in the Neck.—Alvarez regards the swelling of a gland as a sign of defensive reaction on the part of the organism against the invading germs. The gland may conquer and the germs succumb, and Nature has multiplied the number of glands at the points where infection is constantly threatening the frontiers—the skin and mucosæ. Treatment should aim to destroy the microbes imprisoned in the reacting gland, either by excision of the gland or by medical means. The latter includes the warding off of new infection by asepsis of the environment and antisepsis of the region through which the germs gain access to the glands. For the glands in the neck and under the jaw, this region is the skin and pharynx. The defensive reaction on the part of the gland is promoted, Alvarez asserts, by fomentation of the region with a saturated salt solution, general tonics and the stimulants of nutrition: air, light and electricity. He has frequently succeeded with these simple medical measures in curing groups of inflamed glands in the neck which otherwise would have required mutilating operations on account of their size and number and the long duration of the process.

19 *The Hymen after Defloration. (L'hymen apres la défloration.) F. Jayle.
20 *Over-and-over Suture of Pedicles, etc., Preferred to Ligatures. (L'hémostase par la suture en surjet pour les pédicules vasculaires et les petits vaisseaux.) H. Chaput.
21 *Acute Hemorrhagic Pancreatitis. R. Leriche and L. Arnaud.
22 Villous Tumor of the Rectum. Vautrin.
23 *Diagnosis and Treatment of Stone in Female Lower Ureter. (Calculs de l'uretère pelvien chez la femme.) S. Pozzi and R. Proust.

19. The Hymen After Deflowering.—Jayle's article is accompanied by 33 illustrations. A number of conclusions are drawn which are important for legal medicine.

20. Over-and-Over Suture Instead of Ligature for Hemostasis.—Chaput gives illustrations showing the excellent effect obtained by an over-and-over suture and then tying the ends of the thread together. This draws the stump of the vessel up into a cone; this suture is easily applied; never slips, like a ligature; never sloughs off, and this method of hemostasis, he declares, should be preferred for all deep pedicles and small vessels which it is difficult to ligate in the depths of the wound.

21. Acute Hemorrhagic Pancreatitis.—Leriche reviews 96 cases of acute hemorrhagic pancreatitis on record, including some from his own practice, in all of which operative treatment was applied, with the cure of 25 patients. The patients not operated on all died. In 2 cases a second operation was required and the patients recovered. A secondary operation may be necessary also on account of gall-stones. In a number of the cases the patients have been in good health for years since the operation, the digestion practically normal. He discusses in detail the etiology, symptoms, diagnosis and treatment, adding four pages of bibliography. The pancreas is generally found more or less pathologic, the influence of gall-stones superposing another prominent factor for the acute syndrome. Changes in the circulation in the gland are the direct cause of the trouble, supplemented by the autodigesting action of the retained kinase of the pancreatic juice. The symptoms at first are generally those of liver colic, but the pain grows worse and persists, the location changing from the liver to the pancreas region; or the trouble may begin without a prodrome with intense pain in the epigastrium. It was so severe in some cases that the patient fainted. Death ensued in less than an hour after the first sign of trouble in Lenormant's case. The pain may radiate extensively but not into the shoulder. The temperature may be above or below normal; the pulse is slow, hard and firm, like the pulse of lead colic. Vomiting may occur at first but ceases later. The affection is rare in France, only 5 or 6 cases having been reported in the last three years, and it is rare likewise in Spain, Italy and Hungary; it seems to be most prevalent among people inclined to corpulence.

23. Stone in the Lower Ureter in the Female.—Pozzi gives a profusely illustrated summary of 91 cases in the literature, including 2 from his own experience, with especial regard to Roentgen and other means of differentiation and the best mode of access to the calculus. The calculus in one of his cases weighed 34.57 gm. and was 11 cm. long. He also discusses the cases of inflammation in and around the ureter simulating a calculus in various respects. In one such case two phleboliths cast a single shadow suggesting a ureter stone. Granulations in the bladder wall may also simulate ureter calculi in the skiagraph. Paraintestinal concretions may likewise prove deceptive in this way, as he shows by illustrations. Another source of error in one case was a cyst in the broad ligament with a cheesy center. In the cases reported the calculus was removed by a transvesical operation in 7, by nephrotomy in 8, by ureterotomy in 47, a combination of the 2 latter in 5, and by expulsion or extraction through the natural passages in 6 and 7 respectively.

Semaine Médicale, Paris

November 17, XXIX, No. 46, pp. 541-552

24 *Local Applications of Alcohol in Typhoid. L. Cheinisse.
25 Cleansing and Disinfection of the Sebaceous Glands by the Electric Current. E. H. Blanc.

24. Advantages of Alcohol Compresses in Treatment of Typhoid Fever.—Cheinisse protests against the routine use of the cold tub-bath in typhoid fever without individualizing, especially for children. The lifting of the patient is liable to do harm, while the action of the bath on the heart cannot be foreseen. Méry warns that the heart action must be closely supervised in children during the bath treatment, and in typhoid more than in any other disease. Cheinisse quotes Variot, Netter, Barbier and others who go still further and denounce the Brand method completely where children are concerned, on account of the frequency of cardiac complications in typhoid in children. Cheinisse regards the handling of the child in giving the baths as liable to favor hemorrhage and perforation, the emaciated abdominal wall of the child affording comparatively slight protection. He prefers treatment with alcohol compresses applied to the abdomen and has never witnessed any inconveniences from them while the course of the disease was rendered milder, the heart was stimulated instead of depressed, and convalescence was hastened. A pad of absorbent cotton or gauze in eight thicknesses is wrung out of 85 per cent. alcohol (90 per cent. for adults), and applied to the abdomen and covered with a gauze compress or cotton pad wrung out of cold water; over this there is an air-tight covering, the whole being held in place with a flannel band. The water compress is renewed every hour, the alcohol compress every two hours. He has applied this technic in twelve severe cases and has been much gratified with the result, the typhoid being modified into a milder form although no marked effect on the temperature was evident. These alcohol compresses were advocated originally by Salzwedel for phlegmons, and they have been used by Russian physicians and others in treatment of peritonitis and appendicitis, with good results. Cheinisse quotes Meyer's report of the cure of tuberculous peritonitis by this means alone; the active hyperemia induced attracts reserve forces to the disease focus, while the alcohol absorbed has a stimulating action on the heart. Last March Cheinisse witnessed the prompt recovery of a girl of 11 under the alcohol compresses which had evidently been effectual in transforming a severe typhoid with high fever and alarming nervous manifestations into a milder form, in which complete recovery ensued in a month. While in charge of this case he was called to see another child, about the same age, with slight bronchitis, high fever and a little rumbling in the right iliac fossa. He diagnosed typhoid and ordered alcohol compresses. This diagnosis was not accepted by the family and another physician was called who confirmed the diagnosis of typhoid, but ordered Brand treatment which was applied. Cheinisse received an urgent summons ten days later and found the child suffering from perforation peritonitis to which he succumbed notwithstanding immediate removal to a hospital and operation. These two cases occurring simultaneously, one with a threatening onset but prompt recovery under the alcohol, the other commencing mildly but terminating fatally under Brand treatment, have confirmed him in his advocacy of the local application of alcohol.

Beiträge zur Klinik der Tuberkulose, Würzburg

26 *Arneth's Neutrophile Leucocyte Formula in Diagnosis of Tuberculosis, etc. (Bluntuntersuchungen nach der Arnethschen Methode im allgemeinen und in der Tuberkulose im speziellen: 102 von uns untersuchte Fälle.) K. Dluski and M. Rospedzihowski.
27 *Paravertebral "Bronchial Gland" Dulness in Early Diagnosis
of Tuberculosis. Inter-
skapularraum und und
spezifische Therapi

26. **Neutrophile Leucocytes According to Arneth's Formula in Tuberculosis.**—This extensive monograph fills 74 pages, giving an impartial summary of the opinions for and against *Arneth's explanation of the blood picture in infectious diseases* and the proportions of the neutrophile leucocytes as characteristic for various affections. The fundamental idea is that the older polynuclear cells are the antitoxin-bearers or producers and that the degree in which they are destroyed by the action of the infection is characteristic, both for the specific affection and for the resisting powers. Arneth's formula was explained in The Journal in 1904, xlii, 494, and xliii, 577. Dluski reports the findings in respect to this formula in 102 cases of tuberculosis and in a large number of other affections. The bibliography of the subject is also given in full. The findings were constant in the tuberculous patients, while nothing of the kind was observed in 10 healthy controls. The findings were strictly in accordance with Arneth's premises in only 86 of the cases, but this number is too large to be a mere coincidence. His formula has undoubtedly a solid scientific basis. In the 86 cases mentioned the formula varied with the progress of the disease or recovery.

27. **Paravertebral Dulness in the Interscapular Space as Early Sign of Tuberculosis.**—Kraemer has for years noticed in certain cases changes in the resonance between the spine and the angle of the scapula with other signs of a lesion in the lung. The cause of the dulness is some affection in the bronchial glands which does not become manifest by percussion until the circulation of the blood and lymph is interfered with in the region. This "bronchial-gland dulness" between the shoulder blades is one of the most frequent signs of tuberculosis and the findings are confirmed by Roentgen examination. The changes in this dulness under tuberculin treatment are an index of the results being obtained. Discovery of this anomaly in the bronchial glands enables successful tuberculin treatment of the tuberculous process to be applied in its incipiency, without interfering with the usual occupation of the patient. He adds several skiagrams showing the shrinking of the area of dulness in the course of treatment of some patients and its extension in the uncontrollable cases.

Stomatitis. (Die pleomorphen
des Zahnbelages und die fusi
Beust.
35 Microscopic-Bacteriologic Diagnosis of Gonorrheal Infection. K. Kutscher.

28. **Prophylaxis of Tuberculosis.**—Czerny thinks that great harm is done by not informing patients that they have tuberculosis when it is discovered. He also insists that the necessity for examining the health of domestics who care for young children is as imperative as in examining for a wet nurse.

30. **Walking Case of Epidemic Meningitis.**—Géronne has encountered a case of epidemic cerebrospinal meningitis which was not so severe as to interfere with the young man's continuing at his business as cashier in a lumber firm. The disease lasted for about two months.

32. **The Results of Correction of Hump.**—Wollenberg gives an illustrated description of two cases in which a severe curvature of the spine from spondylitic kyphosis was successfully reduced. Extension with cautious, graded pressure applied perpendicularly to the hump gave good results.

GENERAL INDEX

All *reading matter* in The Journal from July to December, 1909, inclusive, is indexed here. (For Current Medical Literature Index see pages 2218 to 2270). "Deaths," "Book Notices" and "Society Proceedings" are indexed under these titles at the ends of the letters "D," "B" and "S." Matter pertaining to the Association is under "American Medical Association." With the above exceptions, all matter is indexed under the most important word of the heading that was used in The Journal, and also under the subject heading. For instance, abscess of brain will be found indexed under "abscess" as well as under "brain." Such titles as "ocular manifestations, etc.," have been indexed under "eye." Cross references have been made wherever this was possible. It is also well to remember that, in looking up a certain subject, related words should be consulted, for example, chest, thorax; skull, cranium; bowel, intestines. The letters used to explain in which department the matter indexed appeared are as follows: "E" editorial; "O" original article; "C" correspondence; and "ab" denotes an abstract of an article that has appeared in full elsewhere. *Names of authors* of original articles appearing in The Journal are not given in this index, but are included in the Index of Authors.

Bacteriolysis of tubercle bacilli, 1604—ab
Bacteriotherapy: See Vaccine Therapy
Bacterium welchii, toxic and antigenic properties of, 1432—ab
Bacteriuria of renal origin, and tubal abscess of unusual position, 814-ab
Balance, question of, 80—ab
Banti's Disease: See Splenic Anemia
Barium, elimination of, 1862—ab
Baths and exercises in abnormal tension of heart and blood vessels, 325—ab
  hot, influence of, on pulse frequency blood pressure, body temperature, breathing volume and alveolar tension in man, 2116—ab
  shower, portable, 801—ab
Battery, dry-cell, method of increasing efficiency and life of, 1205—C
Battle casualty and disease, 1768—ab
Bed rest in nervous dyspepsia, 14—ab
Beef and meat juices, report of Council on Pharmacy and Chemistry on, 1754
  juices and meat extracts, 1744—E. 2021—C
Belt, Momburg, constriction, for exarticulation of hip and part of pelvis, 980—ab
Belt, Momburg, constriction, ineffectual for postpartum hemorrhage, 663—ab
  Momburg, constriction, to arrest hemorrhage, 1519—ab
Benzidin and guaiac tests, comparison of, for occult hemorrhage in diseases of digestive organs, 75—ab
Benzosalin, 868
Bergen, description of, 1045—ab
  letter, 961
Beriberi, crew disabled by, 126
  in England, 1302
Berlin letter, 40, 127, 217, 392, 568, 641, 727, 807, 880, 960, 1040, 1112, 1198, 1302, 1411, 1575, 1652, 1753, 1834, 1927, 2111, 2170
  University centennial of, 880
Bier's Hyperemia: See Hyperemia
Bile, bacteriolytic action of, on pneumococcus, 636—E
  ducts, reconstruction of 774—O, 803—E, 1188—O
  effect of injection of, on circulation, 1333—ab
  filter paper test for, in gastric contents, 310—C
  pigment, tests for, in urine, 1141-ab
  salts, 1405—E
  salts and holadin, 530
  salts commercial purity of 1412—O
  salts, experimental injection of, causing ulceration of stomach and necrosis of salivary glands, 2036—ab
Bilein, 2101
Bilharzial conditions, interesting, 1782—ab
Biliary tract, surgery of, 153—ab
  tracts, advantages of cholecystostomy in draining, 1127—ab
Biology as basis of infant feeding, 2034—ab
Binder, pelvic, open-seat, 1512—ab
Binding journal in four books a year, 883
Binocular spacial pole, 1042—C
Birth-rate, falling, 1833
  of various nationalities, 1303
Births, record of, commissioner of health authorized to correct name in, 484—ab
Bismuth beta-naphtholate, 2101, 2111—O
  gauze, in gynecologic work, 1397—O
  paste for fistulas, 899—ab
  paste, in tuberculous sinuses, 478-ab
  poisoning and non-toxic substitute for bismuth, 85—ab
  subnitrate vaselin paste, poisoning from, 1515—ab
  substitute for, in x-ray work, 333-ab
Bitters, action of, on absorption in gastrointestinal tract, 155—ab
Blackwater Fever: See Hemoglobinuric Fever
Bladder calculi, recurrence of, after removal in 160 operations, 82—ab
  exstrophy of, Maydl's operation for, 574—ab
  exstrophy of, results of treatment of, 1326—ab
  exstrophy of, treated by extraperitoneal implantation of ureters into rectum, end-results of intestinal implantation, 1434—ab
  exstrophy of, treatment of, 979—ab
  extirpation of, 1325—ab
  faradization of, in tabes dorsalis, 1521—ab
  fat as foreign body in, benzin to dissolve, 1065—ab
  hernia of, 158—ab, 633—O
  male, technic of resection of, 1946—ab
  male, unique foreign body in, removal by suprapubic cystotomy, 1861—ab
  neoplasms, transperitoneal operation for removal of, 2146—O
  or ureter, method of opening into, through vagina without risk of fistula, 900—ab
  resection of, for malignant disease, 2037—ab
  resections, 2035—ab
  symptoms due to diseases external to, 1861—ab
  tuberculosis of, 77—ab, 236—ab
  tumors, surgical treatment of, 1217—ab, 1944—ab
Blastomycosis and coccidioidal granuloma in central nervous system, 1431—ab
Bleaching-powder, purification of water with, 1293—E
Bleeding: See Hemorrhage
Blennorrhea: See Gonorrhea
Blindness in Hamilton County, Ohio, 972—ab
  pregnancy, 1952—ab
  unnecessary, 1849—ab
Blond race, dolicho-cephalic, fate of, 1833
Blood and thunder, 35—ab

Blood and urine, influence of x-ray on composition of, in mixed cell leucemia, 1787—ab
  and urine, lactic acid in, in epilepsy and eclampsia, 596—ab
  bacteriology of, in convalescence from typhoid, with theory of pathogenesis of the disease, 592-ab
  child's, viscosity, hemoglobin and albumin content of, 1951—ab
  clinical importance of determination of antitrypsin in, 661—ab
  coagulation of, 488—ab
  coagulation time of, factors influencing, 1434—ab
  concentration of, in infants, 1341-ab
  corpuscles, enumeration of, by simplified methods, 2039—ab
  corpuscles, red, reticulated, study of, by vital staining methods; its relation to polychromatophilia and stippling, 1431—ab
  count, differential, in eruptive diseases, 978—ab
  cultures, importance of, in study of infections of otitic origin, 1232-ab
  diagnosis of cancer by examination of, 1516—ab
  diagnosis of lead poisoning from, 661—ab
  differentiation, Uhlenhuth's method of, 1312
  examination, value of, 1319—ab
  excessive amount of, protrusion in supraclavicular fossa as sign of, 1867—ab
  expulsion of, from lower part of body by Momburg belt, 331—ab, 822—ab
  films, staining of, 1331—ab
  guaiac test for, in helminthiasis, 1139—ab
  in chorea and rheumatism, 1062—ab
  in exophthalmic goiter, 1144—ab
  in infectious diseases in children, 978—ab
  in progressive peritonitis, 1701—ab
  in surgery, 318—ab
  method for counting bacteria in, 1487—O
  occult, in stool, spectroscopic test for, 660—ab
  of eclamptics, seroreaction in, 245—ab
  of insane, reaction obtainable in, 86—ab
  platelet and megalokaryocyte reactions in rabbit, 591—ab
  plates in malaria, 158—ab
  reactions in lepers, 1125—ab
  serum, antitryptic power of, diagnostic importance of, 658—ab
  serum, influence of concentration on presence of tetanus toxin in, 1332—ab
  serum, isolysin in, with cancer, 902—ab
  serum, Loeffler's, test-tube rack used in preparation of, 382—O
  smears, preparation and staining, 1909—O
  special reaction in, in umbilical cord, 661—ab
  stain technic, Wright, 1580
  test for, 1141—ab
  test, new, 2022
  transfusion as therapeutic measure, 325—ab
  transfusion, direct, by paraffin-coated glass tubes, 1333—ab
  transfusion of minute amounts of, in severe anemia, 1340—ab
  trichina embryos in, 302—E
  Tubercle Bacilli in: See Bacilli
  tuberculous, specific precipitins and auto precipitins in, and influence on them of I K and tuberculin, 1868—ab
  unusual cells in, fatal anemia of unknown cause in child of five with, 591—ab
  vessel surgery, 323—ab
  vessels and organs, transplantation of, 750—ab, 1700—ab
  vessels and heart, abnormal tension of, baths and exercises in treatment of, 325—ab
  vessels, diseases of, suggestions from physiology in treatment of, 653—ab
  vessels, flap method of suturing, 1784—ab
  vessels, great, and heart, orthodiagraphy in study of, 1514—ab
  vessels, mesenteric, pathology and treatment of disturbances in circulation in, 1141—ab
  vessels, ovarian, ligation of, as substitute for oöphorectomy, 746—ab
  vessels, permanent hypertonicity of, 1242—ab
  vessels, pulmonary, action of adrenalin on, 1692—ab
  vessels, suture of, in man, 2043—ab
  viscosity of, in surgical affections and operations, 1787—ab
Blood, viscosity of, variations in, as early sign of cardiac insufficiency, 1144—ab
Blood-pressure, arteriosclerotic variations in, in single individual, 1520—ab
  comparative, in brachial and digital arteries, 246—ab
  determinations, clinical, influence of soft tissues of arm on, 413—ab
  facts on, 1693—ab
  high arterial, treatment and prognosis of, 490—ab
  in general paresis, 892—ab
  lowering of, by nitrite group, 1629—O
  past middle life in diagnosis, prognosis and treatment, 1507—ab
  pulse frequency, body temperature, breathing volume and alveolar tension, influence of hot baths on, in man, 2116—ab
  systemic, effect of compression of superior mesenteric artery on, 1780—ab
  systolic, in man, measurement of, 899—ab
Blushing, morbid, 902—ab
Board of control, Minnesota state, 1849—ab
  of health enjoined from sending elderly women with anesthetic leprosy to pesthouse, personal liability to members of health board, 2128
Body, resistance of, to simple poisons, 1566—E
Boils, 385—ab
  and carbuncles, treatment of, 1599—ab, 1697—ab
Bombay, tuberculosis in, 1947—ab
Bondet, Prof., death of, 469
Bone and joint changes in leprosy, 1125—ab
  and joint disease, acute, in infants, 1339—ab
  diseases, x-ray diagnosis of, 1426-ab
  fragility and eburnation of, in rachitis, 80—ab
  free, plastic operation for pseudarthrosis of neck of femur, 906—ab
  subcutaneous and intramuscular neoformation of, by injection or implantation of an emulsion of periosteum, 492—ab
  temporal, infantile types of, and their surgical importance, 1326-ab
  transference, 1515—ab
  tuberculosis, importance of early recognition of, 322—ab
  tuberculosis, radiotherapy of, 1871—ab
Bones, abnormal development of, 140—ab
  extension of, adjustable drill for, 1244—ab
  long, cysts of, 1132—ab
  long, sarcoma of, conservative treatment, 748—ab
  long, treatment of fractures of, 1138—ab
Book agent, warning against, 1113—C
Books, disinfection of, 491—ab
Boston, higher entrance requirements in, 1212
Bottle in rectum, 383—O
Bowels: See also Intestines
Bowels, diet and care of, in typhoid, 1514—ab
Boy of 15, catalepsy in, 238—ab
Bradycardia, extreme, and acetonuria with severe intoxication, 143—ab
